

CMOS 16-Bit Microcontrollers

TMP95CU54AF

1. Outline and Features

The TMP95CU54A is a high-speed 16-bit microcontroller designed for the control of various mid-to large-scale equipment.

The TMP95CU54A comes in a 100-pin flat package.

Listed below are the features of the TMP95CU54A.

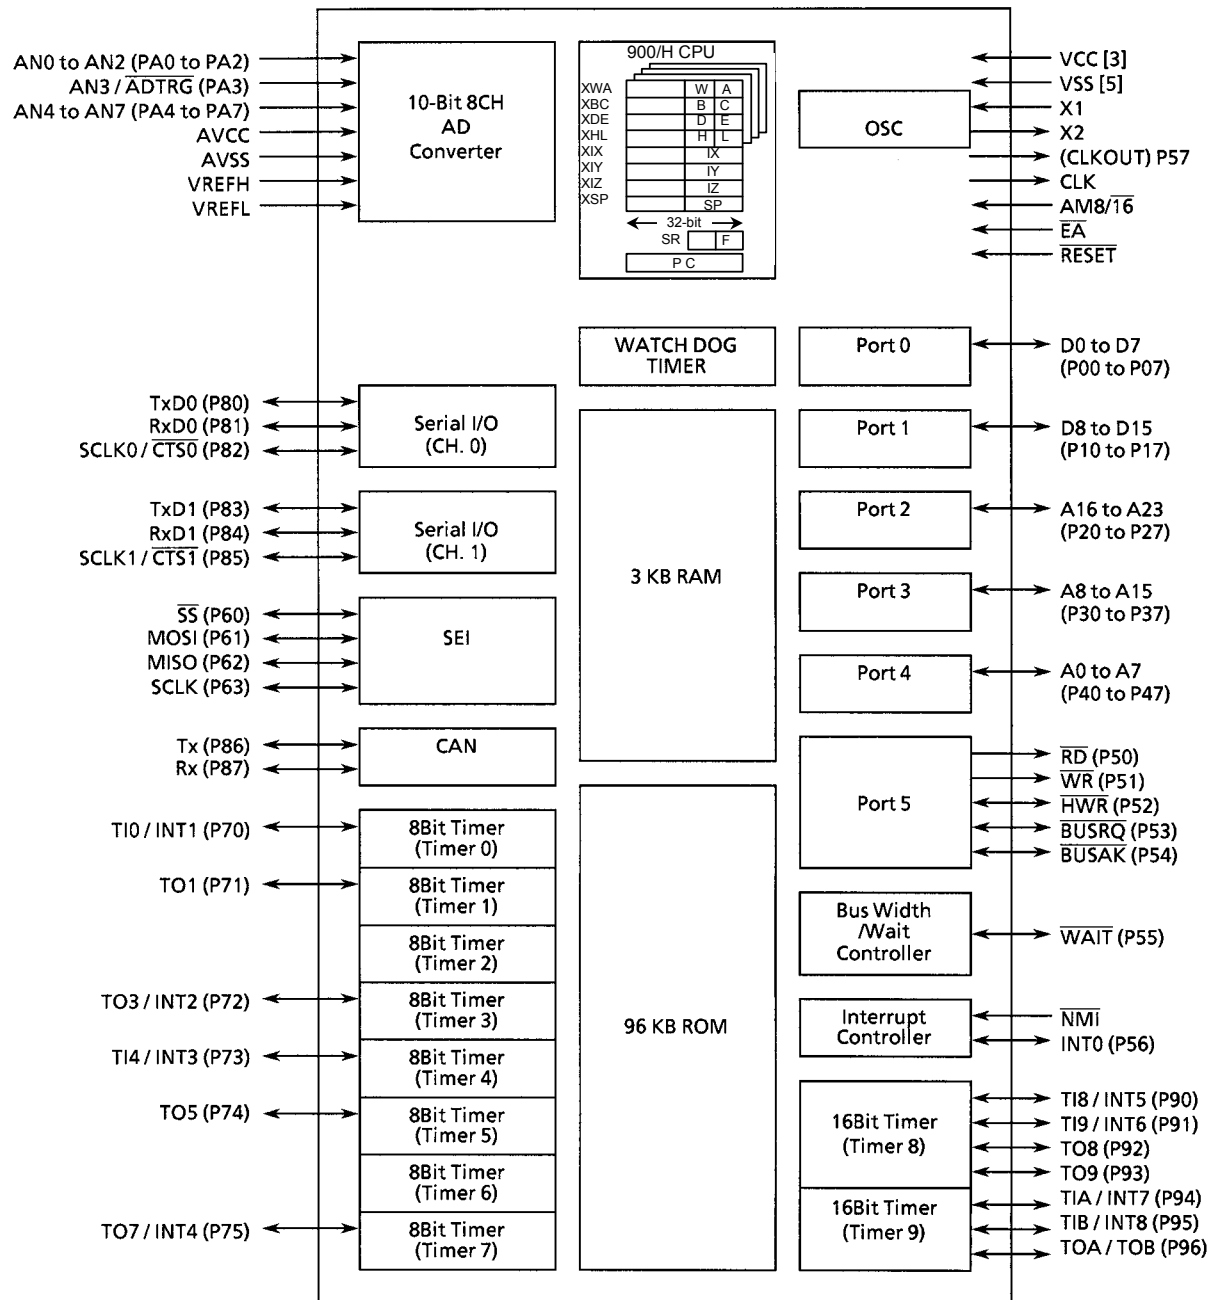

- (1) High-speed 16-bit CPU (900/H CPU)
 - Instruction mnemonics are upward-compatible with the TLCS-90/900
 - 16 Mbytes of linear address space
 - General-purpose registers and register banks
 - 16-bit multiplication and division instructions; bit transfer and arithmetic instructions
 - Micro DMA : Four-channels (667 ns/2 bytes at 24 MHz)
- (2) Minimum instruction execution time : 167 ns (at 24 MHz)
- (3) Built-in RAM : 3 Kbytes
Built-in ROM : 96 Kbytes
- (4) External memory expansion
 - Expandable up to 16 Mbytes (shared program/data area)
 - External data bus width select pin (AM8/ $\overline{16}$)
 - Can simultaneously support 8/16-bit width external data bus
... Dynamic data bus sizing
- (5) 8-bit timers : 8 channels
 - With event counter function : 2 channels
- (6) 16-bit timer/event counter : 2 channels

RESTRICTIONS ON PRODUCT USE

030619EBP

- The information contained herein is subject to change without notice.
- The information contained herein is presented only as a guide for the applications of our products. No responsibility is assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of TOSHIBA or others.
- TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.
In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc..
- The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunction or failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc.. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk.
- The products described in this document are subject to the foreign exchange and foreign trade laws.
- TOSHIBA products should not be embedded to the downstream products which are prohibited to be produced and sold, under any law and regulations.
- For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions.

- (7) General-purpose serial interface : 2 channels
- (8) Serial Expansion Interface : 1 channel
- (9) CAN Controller : 1 channel
- (10) 10-bit AD converter : 8 channels
- (11) Watchdog timer
- (12) Bus width/wait controller : 4 blocks
- (13) Interrupts : 49 interrupts
 - 9 CPU interrupts : Software interrupt instruction and illegal instruction
 - 30 internal interrupts : Seven selectable priority levels
 - 10 external interrupts : Seven selectable priority levels
- (14) Input/output ports : 81 pins
- (15) Standby mode
 - Four HALT modes : RUN, IDLE2, IDLE1, STOP
- (16) Operating voltage
 - $V_{CC} = 4.5$ to 5.5 V
- (17) Package
 - P-LQFP100-1414-0.50D

Note: After a reset, functions in parentheses () are selected for the shared pins.

2. Pin Assignment and Pin Functions

This section shows the TMP95CU54A pin assignment, and the names and an outline of the functions of the input/output pins.

2.1 Pin Assignment Diagram

Figure 2.1.1 is the pin assignment diagram for the TMP95CU54A.

Figure 2.1.1 Pin Assignment Diagram (100-Pin LQFP)

2.2 Pin Names and Functions

Table 2.2.1 shows the names and functions of the input/output pins.

Table 2.2.1 Pin Names and Functions (1/4)

Pin Name	Number of Pins	Input/Output	Function
P00 to P07 / D0 to D7	8	Input/output	Port 0: I/O port. Input or output specifiable in units of bits
		Input/output	Data: Data bus 0 to 7
P10 to P17 / D8 to D15	8	Input/output	Port 1: I/O port. Input or output specifiable in units of bits
		Input/output	Data: Data bus 8 to 15
P20 to P27 / A16 to A23	8	Input/output	Port 2: I/O port. Input or output specifiable in units of bits
		Output	Address: Address bus 16 to 23
P30 / A8	1	Input/output	Port 30: I/O port (with built-in pull-up resistor during input mode.)
		Output	Address: Address bus 8
P31 to P37 / A9 to A15	7	Input/output	Port 31 to 37: I/O port. Input or output specifiable in units of bits
		Output	Address: Address bus 9 to 15
P40 to P47 / A0 to A7	8	Input/output	Port 4: I/O port. Input or output specifiable in units of bits
		Output	Address: Address bus 0 to 7
P50 / $\overline{\text{RD}}$	1	Output	Port 50: Output-only port
		Output	Read: Outputs strobe signal to read external memory (setting P5 <P50> = 0 and P5FC <P50F> = 1 outputs strobe signal at all read timings)
P51 / $\overline{\text{WR}}$	1	Output	Port 51: Output-only port.
		Output	Write: Outputs strobe signal to write data on pins D0 to D7
P52 / $\overline{\text{HWR}}$	1	Input/output	Port 52: I/O port (with built-in pull-up resistor)
		Output	Upper write: Outputs strobe signal to write data on pins D8 to D15
P53 / $\overline{\text{BUSRQ}}$	1	Input/output	Port 53: I/O port (with built-in pull-up resistor)
		Input	Bus request: Input pin to request external bus release
P54 / $\overline{\text{BUSAk}}$	1	Input/output	Port 54: I/O port (with built-in pull-up resistor)
		Output	Bus acknowledge: Output pin to acknowledge that CPU received $\overline{\text{BUSRQ}}$ and released external bus.
P55 / $\overline{\text{WAIT}}$	1	Input/output	Port 55: I/O port (with built-in pull up resistor)
		Input	Wait: Buswait request pin for CPU (Effective when 1 WAIT + N mode, or 0 + N WAIT mode. Set using bus width/wait control register.)
P56 / INT0	1	Input/output	Port 56: I/O port (with built-in pull-up resistor)
		Input	Interrupt request pin 0: Interrupt request pin with programmable level/rising edge.

Table 2.2.1 Pin Names and Functions (2/4)

Pin Name	Number of Pins	Input/Output	Function
P57 /CLKOUT	1	Output	Port 57: Output-only port (with built-in pull-up resistor)
		Output	CLKOUT output: Outputs external clock divided by 6. Pulled up during reset.
P60 /SS	1	Input/output	Port 60: I/O port
		Input	SEI slave select input
P61 /MOSI	1	Input/output	Port 61: I/O port
		Input/output	SEI master output, slave input
P62 /MISO	1	Input/output	Port 62: I/O port
		Input/output	SEI master input, slave output
P63 /SCLK	1	Input/output	Port 63: I/O port
		Input/output	SEI clock input/output
P70 /TI0 /INT1	1	Input/output	Port 70: I/O port
		Input	Timer input 0: Input pin for timer 0
		Input	Interrupt request pin 1: Rising-edge interrupt request pin 
P71 /TO1	1	Input/output	Port 71: I/O port.
		Output	Timer output 1: Output pin for timer 0 or 1
P72 /TO3 /INT2	1	Input/output	Port 72: I/O port
		Output	Timer output 3: Output pin for timer 2 or 3
		Input	Interrupt request pin 2: Rising-edge interrupt request pin 
P73 /TI4 /INT3	1	Input/output	Port 73: I/O port
		Input	Timer input 4: Input pin for timer 4
		Input	Interrupt request pin 3: Rising-edge interrupt request pin 
P74 /TO5	1	Input/output	Port 74: I/O port
		Output	Timer output 5: Output pin for timer 4 or 5
P75 /TO7 /INT4	1	Input/output	Port 75: I/O port
		Output	Timer output 7: Output pin for timer 6 or 7
		Input	Interrupt request pin 4: Rising-edge interrupt request pin 
P80 /TxD0	1	Input/output	Port 80: I/O port (with built-in pull-up resistor)
		Output	Serial transmission data 0
P81 /RxD0	1	Input/output	Port 81: I/O port (with built-in pull-up resistor)
		Input	Serial receive data 0
P82 /SCLK0 /CTS0	1	Input/output	Port 82: I/O port (with built-in pull-up resistor)
		Input/output	Serial clock input/output 0
		Input	Serial data ready to send 0 (Clear-to-send)

Table 2.2.1 Pin Names and Functions (3/4)

Pin Name	Number of Pins	Input/Output	Function
P83 / TxD1	1	Input/output	Port 83: I/O port (with built-in pull-up resistor)
		Output	Serial transmission data 1
P84 / RxD1	1	Input/output	Port 84: I/O port (with built-in pull-up resistor)
		Input	Serial receive data 1
P85 / SCLK1 / CTS1	1	Input/output	Port 85: I/O port (with built-in pull-up resistor)
		Input/output	Serial clock input/output 1
		Input	Serial data ready to send 1 (Clear-to-send)
P86 / Tx	1	Input/output	Port 86: I/O port (with built-in pull-up resistor)
		Output	CAN transmission data
P87 / Rx	1	Input/output	Port 87: I/O port (with built-in pull-up resistor)
		Input	CAN receive data
P90 / TI8 / INT5	1	Input/output	Port 90: I/O port
		Input	Timer input 8: Input pin for timer 8
		Input	Interrupt request pin 5: Interrupt request pin with programmable rising/falling edge 
P91 / TI9 / INT6	1	Input/output	Port 91: I/O port
		Input	Timer input 9: Input pin for timer 8
		Input	Interrupt request pin 6: Rising edge interrupt request pin 
P92 / TO8	1	Input/output	Port 92: I/O port
		Output	Timer output 8: Output pin for timer 8
P93 / TO9	1	Input/output	Port 93: I/O port
		Output	Timer output 9: Output pin for timer 8
P94 / TIA / INT7	1	Input/output	Port 94: I/O port
		Input	Timer input A: Input pin for timer 9
		Input	Interrupt request pin 7: Interrupt request pin with programmable rising/falling edge 
P95 / TIB / INT8	1	Input/output	Port 95: I/O port
		Input	Timer input B: Input pin for timer 9
		Input	Interrupt request pin 8: Rising edge interrupt request pin 
P96 / TOA / TOB	1	Input/output	Port 96: I/O port
		Output	Timer output A: Output pin for timer 9
		Output	Timer output B: Output pin for timer 9
PA0 to PA2 / AN0 to AN2	3	Input	Port A0 to A2: Input-only port
		Input	Analog input 0 to 2: AD converter input pins
PA3 / AN3 / ADTRG	1	Input	Port A3: Input-only port
		Input	Analog input 3: AD converter input pin
		Input	External start trigger

Table 2.2.1 Pin Names and Functions (4/4)

Pin Name	Number of Pins	Input/Output	Function
PA4 to PA7 / AN4 to AN7	4	Input	Port A4 to A7: Input-only port
		Input	Analog input 4 to 7: AD converter input pins
$\overline{\text{NMI}}$	1	Input	Non-maskable interrupt request pin: Interrupt request pin with programmable falling edge or both falling and rising edge 
CLK	1	Output	Clock output: Outputs external clock divided by 4. Pulled up during reset.
$\overline{\text{EA}}$	1	Input	External access: Connect to VCC.
AM8 / $\overline{16}$	1	Input	Address mode: External data bus width select pin Connect this pin to VCC. Data bus width at external access can be set by bus width/wait control register.
$\overline{\text{RESET}}$	1	Input	Reset: Initializes TMP95CU54A (with built-in pull-up resistor)
VREFH	1	Input	Reference voltage input pin for AD converter (high)
VREFL	1	Input	Reference voltage input pin for AD converter (low)
AVCC	1		Power supply pin for AD converter: Connect to power supply
AVSS	1		GND pin for AD converter: Connect to GND
X1 / X2	2	Input/output	Oscillator connecting pin
VCC	3		Power supply pin: Connect all VCC pins to power supply
VSS	5		GND pin: Connect all VSS pins to GND (0 V)

Note: Disconnect the pull-up resistors from pins other than $\overline{\text{RESET}}$ pin by software.
P30 is pulled-up during reset and input mode.
P57 and CLK pin are pulled-up only during reset.

3. Operation

The following is a block-by-block description of the functions and basic operation of the TMP95CU54A.

Notes and restrictions for each block are outlined in “7, Use Precautions and Restrictions” on page 276 of this manual.

3.1 CPU

TMP95CU54A incorporates a high-performance 16-bit CPU (900/H-CPU). For CPU operation, see the section dealing with the TLCS-900/H CPU.

The following describes the unique functions of the CPU used in the TMP95CU54A; these functions are not covered in the TLCS-900/H CPU section.

3.1.1 Reset

When resetting the TMP95CU54A microcontroller, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the RESET input to low level for at least 10 system clocks (ten states: 0.83 μ s at 24 MHz).

When the reset is accepted, the CPU:

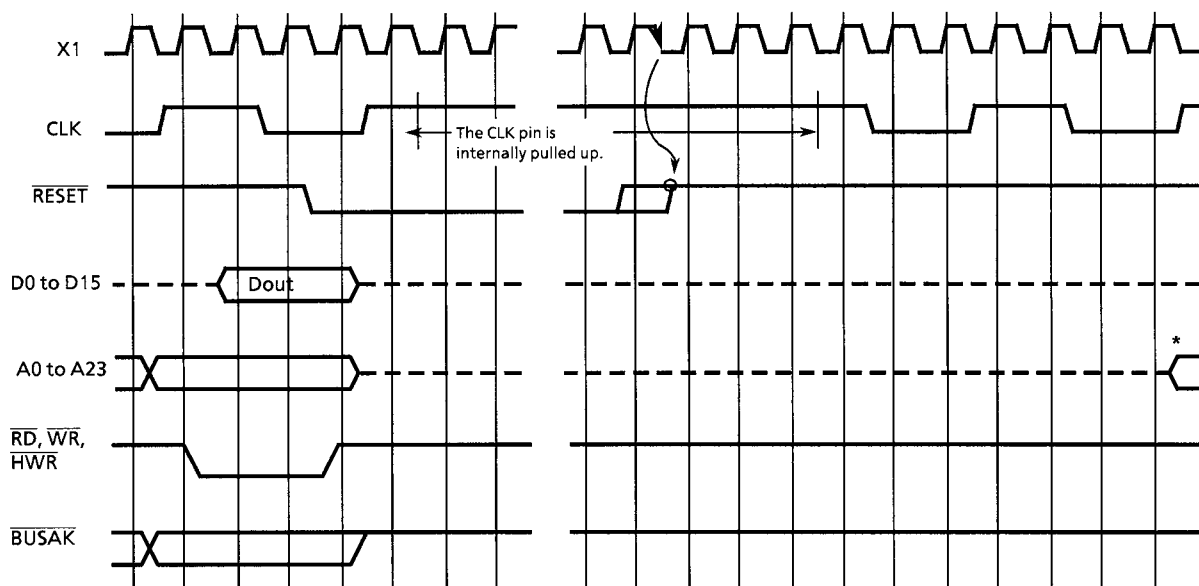

- Sets as follows the program counter (PC) in accordance with the reset vector stored at address FFFF00H - FFFF02H:
PC (7:0) \leftarrow value at FFFF00H address
PC (15:8) \leftarrow value at FFFF01H address
PC (23:16) \leftarrow value at FFFF02H address
- Sets the stack pointer (XSP) to 100H.
- Sets bits <IFF2:0> of the status register (SR) to 111 (sets the interrupt level mask register to level 7).
- Sets the <MAX> bit of the status register to 1 (MAX mode).
(Note: As this product does not support a MIN mode, do not write 0 to <MAX>.)
- Clears bits <RFP2:0> of the status register to 000 (sets the register bank to 0).

When reset is released, the CPU starts executing instructions in accordance with the program counter settings. CPU internal registers not mentioned above do not change when the reset is released.

When the reset is accepted, the CPU sets internal I/O, ports, and other pins as follows.

- Initializes the internal I/O registers.
- Sets the port pins, including the pins that also act as internal I/O, to general-purpose input or output port mode.
- Pulls up the CLK pin to high level.
(Note: During reset, do not reduce the external voltage level as this can cause malfunction.)
- Pulls up the P30 pin to high level.
(Note: During reset, do not reduce the external voltage level as this can cause malfunction.)

Figure 3.1.1 shows an example of the basic timing of the reset operation.

* After confirmation that $\overline{\text{RESET}} = \text{high}$, A0 to A23 are output at the X1 rising edge of the 10th or 12th clock.

Figure 3.1.1 TMP95CU54A Reset Timing Example

3.1.2 External data bus width selection (AM8/16 Pin)

Connect the input pin to VCC. After a reset, this pin accesses ROM by the internal 16-bit bus.

The data bus width for an external access depends on the setting in the $\langle \text{B0BUS} \rangle$, $\langle \text{B1BUS} \rangle$, $\langle \text{B2BUS} \rangle$, $\langle \text{B3BUS} \rangle$ or $\langle \text{BEXBUS} \rangle$ bit of the bus width/wait control registers. To access the 16-bit bus, set port 1 to D8 to D15.

3.2 Memory Map

Figure 3.2.1 shows the memory map and the access widths for the CPU addressing modes.

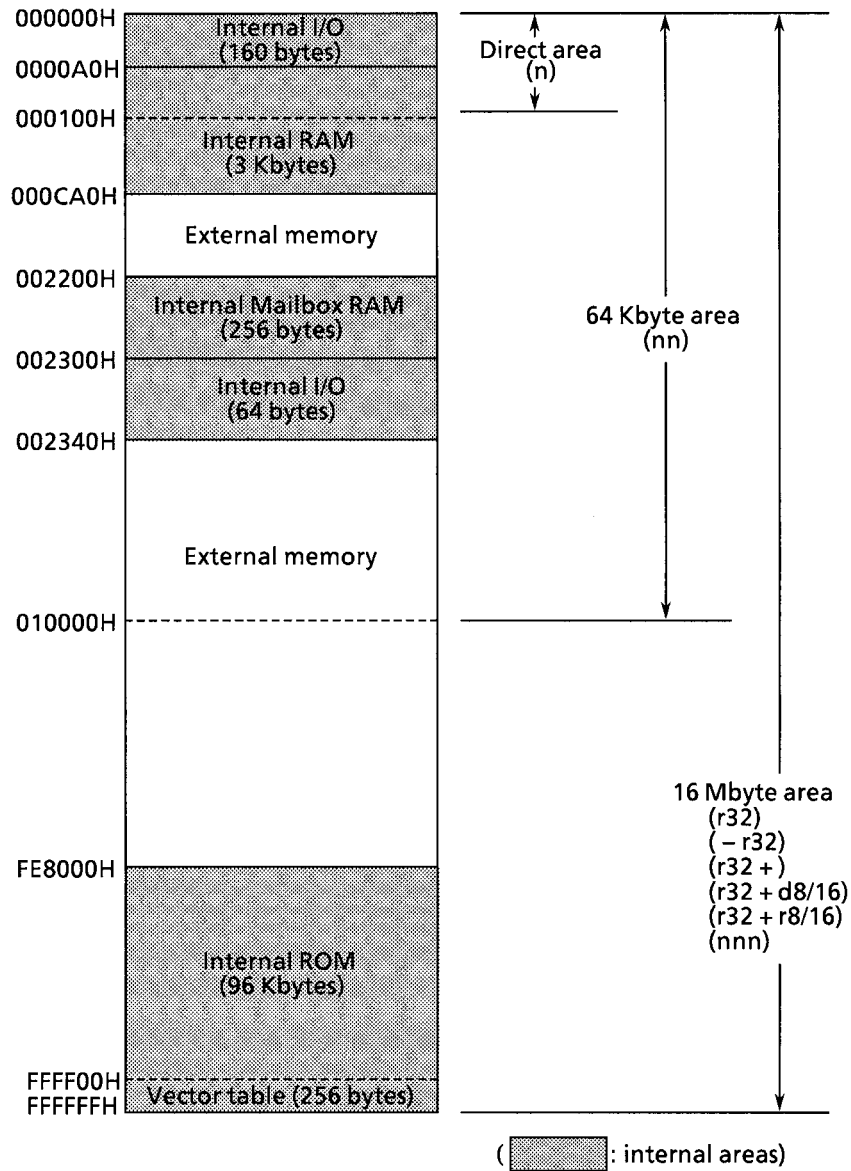

Figure 3.2.1 TMP95CU54A Memory Map

3.3 Interrupts

Interrupts are controlled by the CPU interrupt mask register <IFF2:0> (bits 14 to 12 of the status register) and by the built-in interrupt controller.

The TMP95CU54A has a total of 49 interrupts divided into the following five types:

Interrupts generated by CPU : 9

- Software interrupts : 8
- Illegal instruction : 1

Internal interrupts : 30

- Internal I/O interrupts : 26
- Micro DMA transfer end interrupts : 4

External interrupts : 10

- Interrupts from external pins ($\overline{\text{NMI}}$, INT0 to INT8)

A (fixed) individual interrupt vector number is assigned to each interrupt.

One of seven (variable) priority levels can be assigned to each maskable interrupt. The priority level of non-maskable interrupts is fixed at 7, the highest level.

When an interrupt is generated, the interrupt controller sends the priority of that interrupt to the CPU. If multiple interrupts are generated simultaneously, the interrupt controller sends the interrupt with the highest priority to the CPU. (The highest priority possible is level 7, used for non-maskable interrupts.)

The CPU compares the priority level of the interrupt with the value of the CPU interrupt mask register <IFF2:0>. If the priority level of the interrupt is higher than the value of the interrupt mask register, the CPU accepts the interrupt. However, software interrupts and illegal instruction interrupts generated by the CPU are processed without comparison with the <IFF2:0> value.

The interrupt mask register <IFF2:0> value can be updated using the value of the EI instruction (executing EI num sets the content of <IFF2:0> to num). For example, specifying EI 3 enables the acceptance of maskable interrupts whose priority level set in the interrupt controller is 3 or higher, and enables the acceptance of non-maskable interrupts. However, if EI or EI 0 is specified, maskable interrupts with a priority level of 1 or higher and non-maskable interrupts are accepted (operationally identical to “EI 1”).

Operationally, the DI instruction (<IFF2:0> is 7) is identical to the EI 7 instruction, but as the priority level of maskable interrupts is 0 to 6, the DI instruction is used to disable maskable interrupts. The EI instruction is valid immediately after execution begins. (With the TLCS-90, the EI instruction is valid after execution of the instruction following the EI instruction.)

In addition to the general-purpose interrupt processing mode described above, the TLC95-900/H interrupts also have a micro DMA processing mode.

Because the CPU transfers data (byte transfer, word transfer, or 4-byte transfer) automatically in micro DMA mode, this mode can be used for speeding up interrupt processing, such as transferring data to I/O.

The TMP95CU54A also has a micro DMA soft start function for requesting micro DMA processing by software rather than by interrupt.

Figure 3.3.1 shows the overall interrupt processing flow.

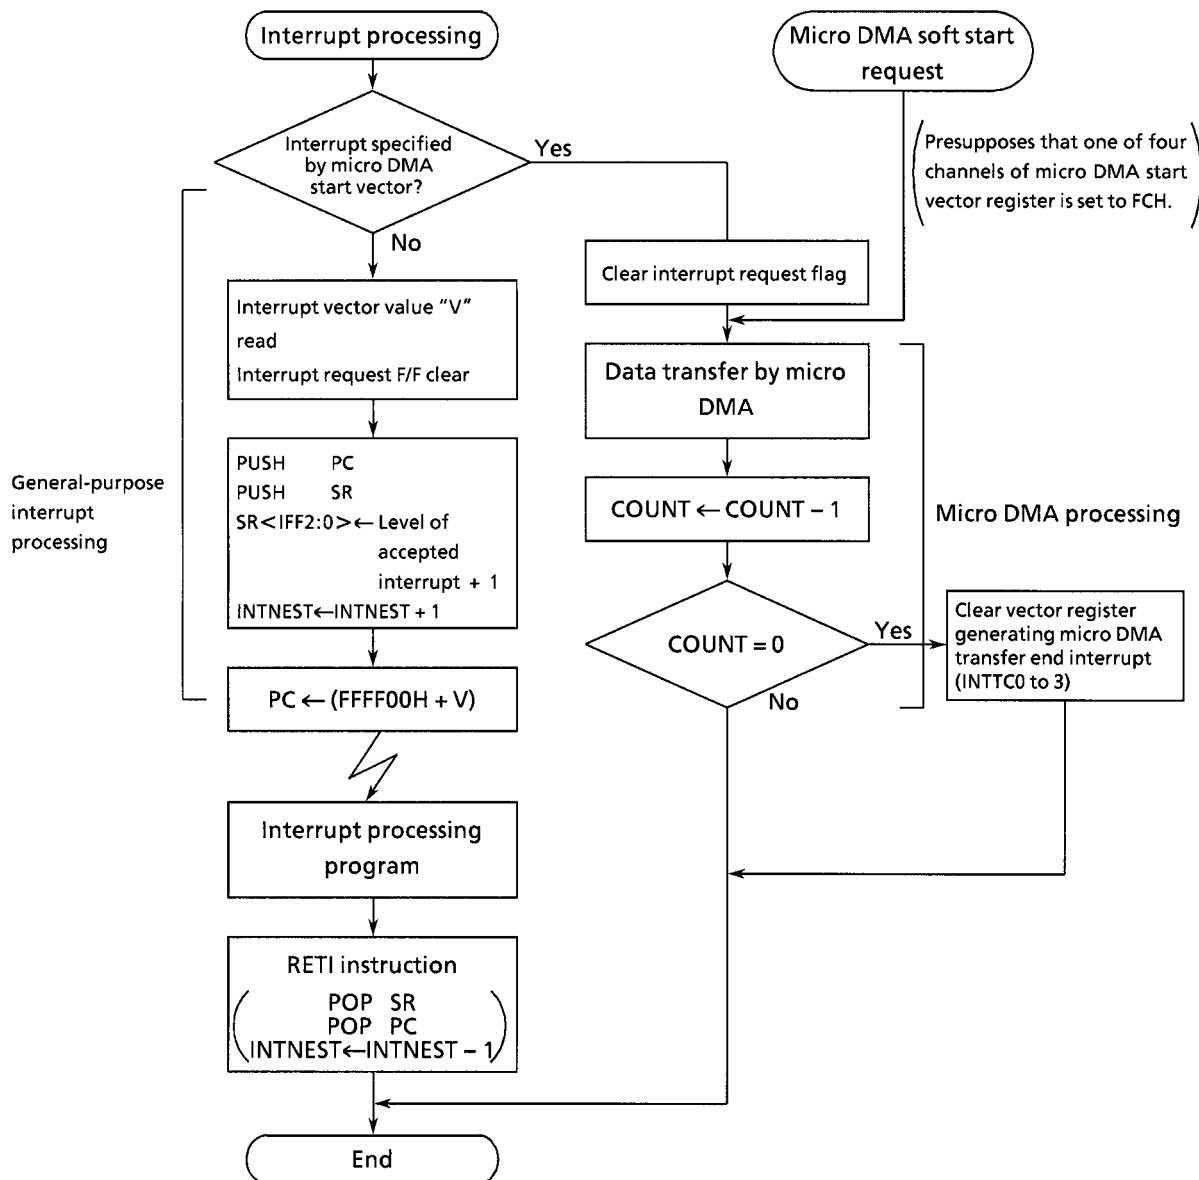

Figure 3.3.1 Interrupt and Micro DMA Processing Flow

3.3.1 General-purpose interrupt processing

When the CPU accepts an interrupt, the CPU performs the following processing. However, in the case of software interrupts and illegal instruction interrupts generated by the CPU, the CPU skips [1] and [3] and executes steps [2], [4], and [5].

- [1] The CPU reads the interrupt vector from the interrupt controller. If there are simultaneous interrupts set to the same level, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt request.
(The default priority is already fixed for each interrupt: the smaller the vector value, the higher the priority level.)
- [2] The CPU saves the contents of the program counter (PC) and status register (SR) to the stack area (indicated by XSP).
- [3] The CPU sets the value of the CPU's interrupt mask register <IFF2:0> to the received interrupt level incremented by 1. However, if the incremented value level is 7 or higher, the CPU just sets the register to 7.
- [4] The CPU increments interrupt nesting counter INTNEST by 1.
- [5] The CPU jumps to the address indicated by the data at address FFFF00H + interrupt vector, and starts the interrupt processing routine.

Table 3.3.1 shows the times for the above processing.

Table 3.3.1 Interrupt Processing Times for Bus Widths

Stack Area Bus Width (Bits)	Interrupt Vector Area Bus Width	Number of Interrupt Processing Execution States	Interrupt Processing Time (μ s) @ $f_c = 24$ MHz
8	8	28	2.33
	16	24	2.00
16	8	22	1.83
	16	18	1.50

When the CPU has completed the interrupt processing, use the RETI instruction to return to the main routine. This instruction restores the contents of the program counter and status register from the stack, and decrements interrupt nesting counter INTNEST by 1.

Non-maskable interrupts cannot be disabled by program. Maskable interrupts can be enabled or disabled by program. The program can set a priority level for every interrupt source. (Setting the priority level to 0 (or 7) disables the interrupt request.)

If a request is received for an interrupt with a higher priority level than that set in the CPU interrupt mask register <IFF2:0>, the CPU accepts the interrupt. Set the CPU interrupt mask register <IFF2:0> to the received interrupt priority level incremented by 1.

If, during interrupt processing, an interrupt is generated with a higher level than the interrupt being currently processed, or if, during non-maskable interrupt processing, a non-maskable interrupt request is generated from another source, the CPU suspends the current processing routine and accepts the later interrupt. Then, after the CPU has finished processing the later interrupt, the CPU returns to the interrupt it previously suspended and resumes processing.

If the CPU receives a request for another interrupt while already performing processing steps [1] to [5], the second interrupt is sampled immediately after execution of the start instruction for its interrupt processing routine. Specifying DI as the start instruction disables maskable interrupt nesting. (Note: In the 900 and 900/L, sampling is performed before execution of the start instruction.)

After a reset, the interrupt mask register <IFF2:0> is initialized to 111, thus disabling maskable interrupts.

The following steps (1) through (5) show the interrupt processing flow.

(1) Maskable interrupts

When the CPU accepts an interrupt, it sets IFF to the priority level of the interrupt incremented by 1.

Accordingly, if during interrupt processing an interrupt request is received with the same or a lower priority than that of the interrupt being processed, because this priority level is lower than the IFF value, the second interrupt cannot be accepted until the processing of the prior interrupt is complete.

Note: (underline): Instruction
 ①, ②, : Execution flow
 IFF: Interrupt mask register

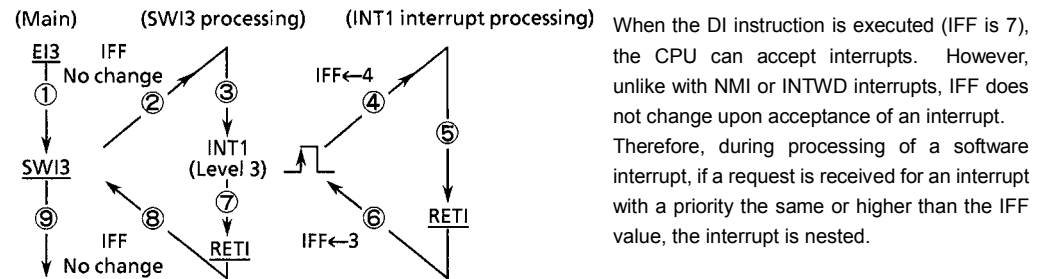

(2) Non-maskable interrupts (NMI, INTWTD)

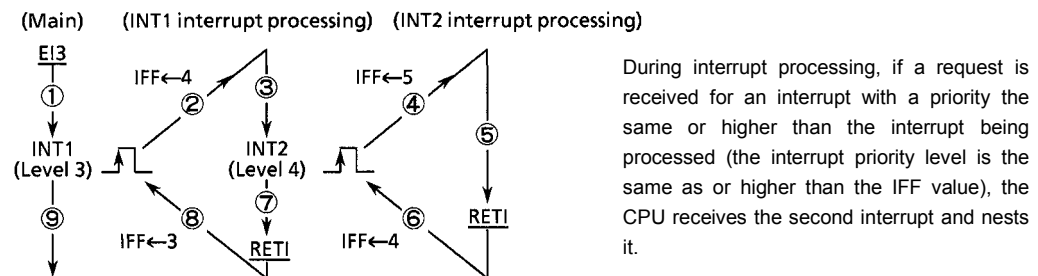

When the DI instruction is executed (IFF is 7), only non-maskable interrupts can be received (because the priority level of non-maskable interrupts is fixed to 7.)

When the EI instruction is executed, the CPU sets IFF to 7 upon acceptance of an NMI or INTWTD interrupt.

(3) Non-maskable interrupts (Software interrupts, illegal instruction interrupts)

(4) Interrupt nesting

(5) Interrupt sampling (Maskable interrupt nesting disabled)

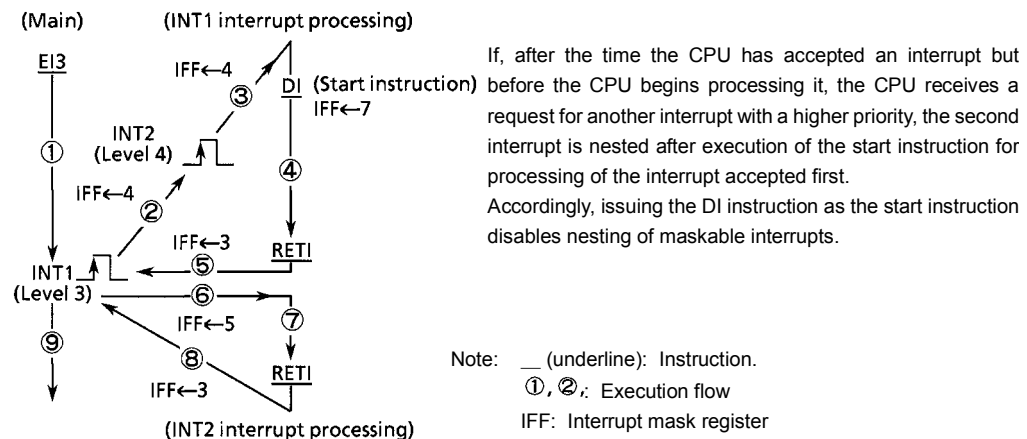

Table 3.3.2 shows the TMP95CU54A interrupt vectors and micro DMA start vectors. With the TMP95CU54A, FFFF00H to FFFFFFFH (256 bytes) is allocated to the interrupt vector area.

Table 3.3.2 TMP95CU54A Interrupt Vectors and Micro DMA Start Vectors

Default priority	Type	Interrupt source and source of micro DMA request	Vector value V	Vector reference address	Micro DMA start vector
1	Non-maskable	Reset or [SWI0] instruction	0 0 0 0 H	FFFF00H	–
2		[SWI1] instruction	0 0 0 4 H	FFFF04H	–
3		Illegal instruction or [SWI2] instruction	0 0 0 8 H	FFFF08H	–
4		[SWI3] instruction	0 0 0 C H	FFFF0CH	–
5		[SWI4] instruction	0 0 1 0 H	FFFF10H	–
6		[SWI5] instruction	0 0 1 4 H	FFFF14H	–
7		[SWI6] instruction	0 0 1 8 H	FFFF18H	–
8		[SWI7] instruction	0 0 1 C H	FFFF1CH	–
9		NMI: NMI pin input	0 0 2 0 H	FFFF20H	–
10		INTWD: Watchdog timer	0 0 2 4 H	FFFF24H	–
–	–	Micro DMA (Note)	–	–	–
11	Maskable	INT0: INT0 pin input	0 0 2 8 H	FFFF28H	28H
12		INT1: INT1 pin input	0 0 2 C H	FFFF2CH	2CH
13		INT2: INT2 pin input	0 0 3 0 H	FFFF30H	30H
14		INT3: INT3 pin input	0 0 3 4 H	FFFF34H	34H
15		INT4: INT4 pin input	0 0 3 8 H	FFFF38H	38H
16		INT5: INT5 pin input	0 0 3 C H	FFFF3CH	3CH
17		INT6: INT6 pin input	0 0 4 0 H	FFFF40H	40H
18		INT7: INT7 pin input	0 0 4 4 H	FFFF44H	44H
19		INT8: INT8 pin input	0 0 4 8 H	FFFF48H	48H
20		INTT0: 8-bit timer 0	0 0 4 C H	FFFF4CH	4CH

to		to	to	to	to
–		(Reserved)	0 0 F C H	FFFFFCH	–
–	–	Micro DMA soft start request	–	–	FCH

Note: Micro DMA default priority

If an interrupt request is generated by a source specified by micro DMA, the interrupt has the highest priority of the maskable interrupts (irrespective of the default priority allocated to all channels).

Setting reset vectors and interrupt vectors

[1] Reset vector

FFFF00H	PC (7:0)	XX: Don't care
FFFF01H	PC (15:8)	
FFFF02H	PC (23:16)	
FFFF03H	XX	

[2] Interrupt vectors (Other than reset vector)

Vector reference address + 0	PC (7:0)	XX: Don't care
+ 1	PC (15:8)	
+ 2	PC (23:16)	
+ 3	XX	

(Setting example)

Where the reset vector is defined as FF0000H, the NMI vector as FF9ABCH, and the INT1 vector as FF3456H

```

ORG    0FF0000H
LD      A, B
      .....
ORG    0FF9ABCH
LD      B, C
      .....
ORG    0FF3456H
LD      C, A
      .....
ORG    0FFFF00H
DL      0FF0000H      ; reset vector = FF0000H

ORG    0FFFF20H
DL      0FF9ABCH      ; NMI vector = FF9ABCH

ORG    0FFFF2CH
DL      0FF3456H      ; INT1 vector = FF3456H

```

Reference:
 ORG and DL are assembler directives
 { ORG: For location counter control
 { DL: To define (32-bit) long word data

3.3.2 Micro DMA processing

In addition to general-purpose interrupt processing, the TMP95CU54A supports a micro DMA function. Interrupt requests set by the micro DMA perform micro DMA processing at the highest priority level of maskable interrupts (level 6), regardless of the priority level of the particular interrupt source.

Because the micro DMA function is implemented with the cooperative operation of the CPU, when the CPU is put into stand-by state by a HALT instruction, micro DMA requirements will be ignored (pending).

(1) Micro DMA operation

When an interrupt request is generated by an interrupt source specified by the micro DMA start vector register, the micro DMA triggers a micro DMA request to the CPU at interrupt priority level 6 and starts processing the request. The four micro DMA channels allow micro DMA processing to be set for up to four types of interrupts at any one time.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. The data are automatically transferred from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented by 1. If the decremented counter reads other than 0, DMA processing ends with no change in the value of the micro DMA start vector register. If the decremented reading is 0, the micro DMA transfer end interrupt (INTTC0 to 3) passes from the CPU to the interrupt controller. In addition, the micro DMA start vector register is cleared to 0, the next micro DMA is disabled, and micro DMA processing is complete.

If a micro DMA request is set for more than one channel at a time, the priority is not based on the interrupt priority level but on the channel number: the smaller the channel number the higher the priority. (Channel 0 (high) --> channel 3 (low)).

If an interrupt request is triggered for the interrupt source in use during the interval between the clearing of the micro DMA start vector and the next setting, general-purpose interrupt processing is executed at the interrupt level set. Therefore, when using the interrupt only for starting the micro DMA (not using the interrupt as a general-purpose interrupt), first set the interrupt level to 0 (interrupt requests disabled).

When using micro DMA and general-purpose interrupts together as described above, first set the level of the interrupt used to start micro DMA processing lower than all the other interrupt levels. In this case, the cause of a general interrupt is limited to the edge interrupt.

Example: When using external interrupt INT0 to 3 to start micro DMA0 to 3, set:

External interrupt INT0 to 3 interrupt level "1"

Level of other interrupts "2" to "6"

As with other maskable interrupts, the priority of the micro DMA transfer end interrupt is determined by the interrupt level and the default priority.

While the register for setting the transfer source/transfer destination addresses is a 32-bit control register, this register can only effectively output 24-bit addresses. Accordingly, micro DMA can access 16 Mbytes (the upper eight bits of the 32 bits are not valid).

Three micro DMA transfer modes are supported: 1-byte transfer, 2-byte (one word) transfer, and 4-byte transfer. After a transfer in any mode, the transfer source/destination addresses are incremented, decremented, or remain unchanged. This simplifies the transfer of data from I/O to memory, from memory to I/O, and from I/O to I/O. For details of the transfer modes, see 3.3.2 (4) Transfer Mode Register.

As the transfer counter is a 16-bit counter, micro DMA processing can be set for up to 65536 times per interrupt source. (The micro DMA processing count is maximized when the transfer counter initial value is set to 0000H.)

Micro DMA processing can be started by the 30 interrupts (INT0 to INTTX1, INTAD, INTSE1, INTSE2) shown in the micro DMA start vectors of Table 3.3.2 and by the micro DMA soft start, making a total of 31 interrupts.

Figure 3.3.2 shows the micro DMA cycle in transfer destination address INC mode (the same as for other modes, with the exception of COUNTER mode).

- [1] Word transfer (the conditions for this cycle are based on an external 16-bit bus, 0 waits, transfer source/transfer destination addresses both even-numbered values)

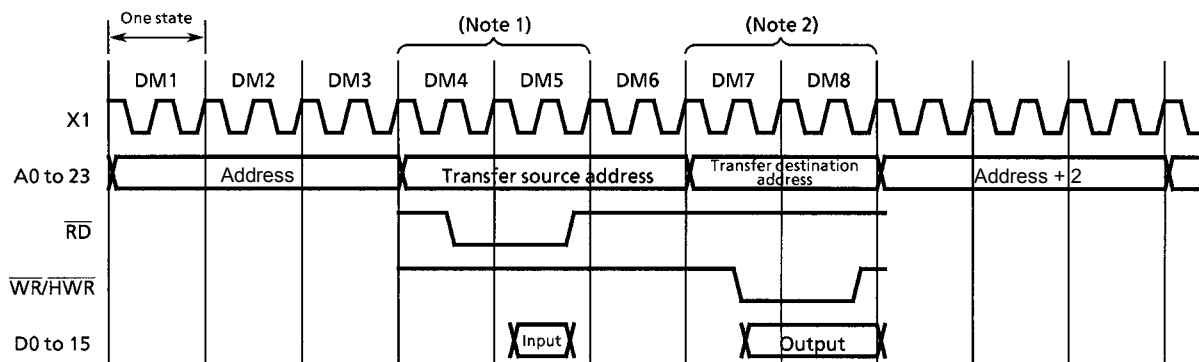

Figure 3.3.2 Timing of Micro DMA Cycle (1/3)

States 1 to 3: Instruction fetch cycle (gets next address code).

If three or more instruction codes are inserted in the instruction queue buffer, this cycle becomes a dummy cycle.

States 4 to 5: Micro DMA read cycle

State 6 : Dummy cycle (the address bus remains as in state 5)

States 7 to 8: Micro DMA write cycle

Note 1: If the source address area is an 8-bit bus, it is incremented by two states.

Note 2: If the destination address area is an 8-bit bus, it is incremented by two states.

[2] Word transfer (the conditions for this cycle are based on a 16-bit external bus, 0 waits, transfer source/transfer destination addresses both odd-numbered values)

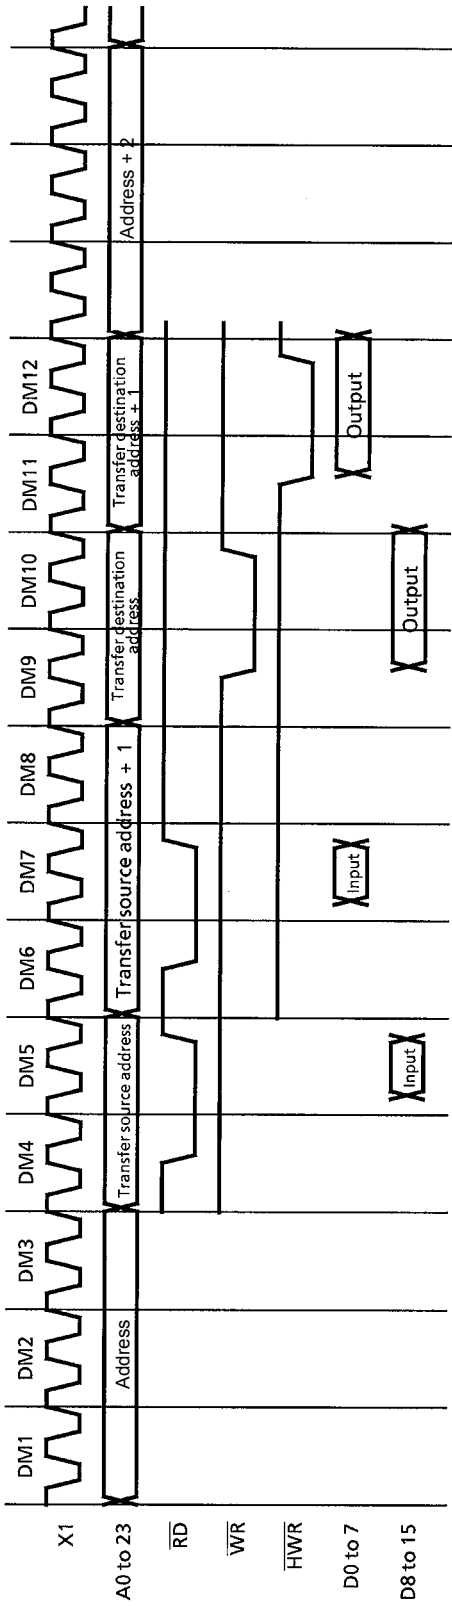

Figure 3.3.2 Timing of Micro DMA Cycle (2/3)

[3] 4-byte transfer (the conditions for this cycle are based on a 16-bit external bus, 0 waits, transfer source/transfer destination addresses both even-numbered values)

Figure 3.3.2 Timing of Micro DMA Cycle (3/3)

(2) Micro DMA soft start function

In addition to starting micro DMA by interrupt, the TMP95CU54A supports a micro DMA soft start function. This starts micro DMA by generating a cycle to write to the soft DMA control register.

To code a soft start, write micro DMA start vector FCH to micro DMA start vector register DMA0V to 3V (at memory addresses 5AH, 5BH, 5CH, and 5DH).

Then, write any data to soft DMA control register SDMACR0 to 3 (at memory addresses 6AH, 6BH, 6CH, and 6DH). (The value of the data has no effect on the operation of the soft start.) This starts micro DMA of the applicable channel once. Then, whenever data are written again to the soft DMA control register, as long as the micro DMA transfer counter register values are other than 0, a soft start can be continuously triggered (without rewriting the micro DMA start vector).

Setting the micro DMA start vector is a prerequisite for generating a micro DMA software start. (The software start request is a one-shot request and not saved. Therefore, even if a cycle which writes to the soft DMA control register is generated, unless the micro DMA start vector is already set, a soft start cannot be generated.)

(3) Structure of micro DMA-only registers

Figure 3.3.3 shows the micro DMA-only registers. These registers are incorporated in the CPU. (See 3.2.5, Control Registers in Chapter 3, TLCS-900/H CPU.) To set the registers use the LDC instruction.

Set the transfer source address in the transfer source address register; the transfer destination address, in the transfer destination address register. These address registers use only the lower 24 bits. They support a 16M-byte address space.

Use the transfer counter register to set the number of times micro DMA is performed between 1 and 65536.

For details on setting the transfer mode register, see 3.3.2 (4), Transfer Mode Register.

Only the LDC cr, r instruction can load data into the micro DMA-only registers.

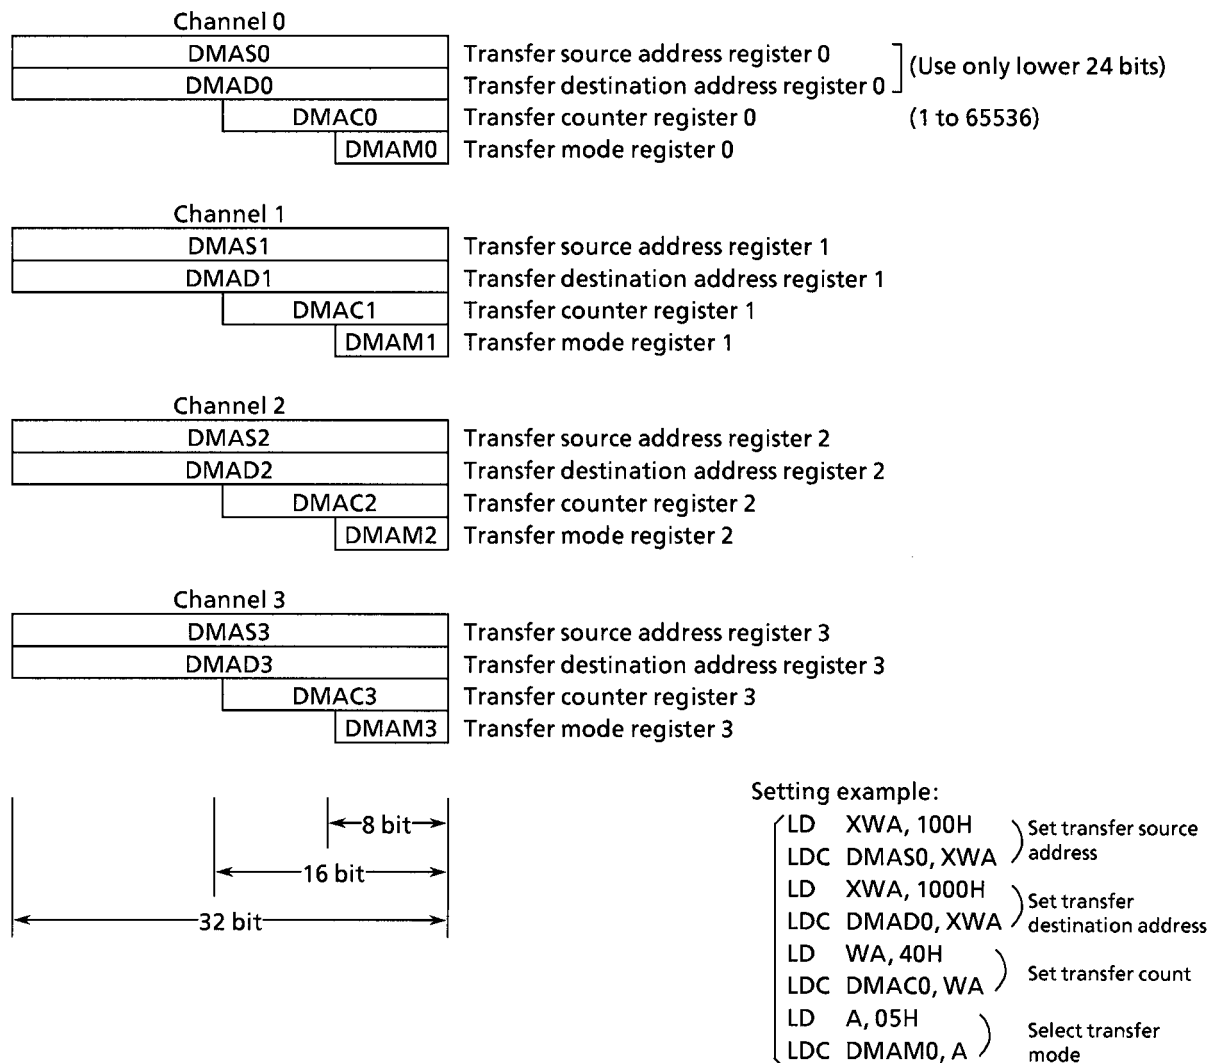

Figure 3.3.3 Micro DMA-Only Registers

(4) Transfer mode register

To set micro DMA transfer mode, use transfer mode register DMAM0 to 3. Table 3.3.3 shows the settings for each mode and the numbers of execution states.

Table 3.3.3 Micro DMA Transfer Mode

DMAM0 to 3			8-bit		Mode	
			0	0	0	
Note: When setting a value in this register, write 0 to the upper three bits.						
			Number of Transfer Bytes	Mode Description	Number of Execution States (*)	Minimum Execution Time @ $f_c = 24$ MHz
000 (Fixed)	000	00	Byte transfer	Transfer destination address INC mode For I/O to memory	8 states	667 ns
		01	Word transfer	(DMADn +) \leftarrow (DMASn)		
		10	4-byte transfer	DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		
	001	00	Byte transfer	Transfer destination address DEC mode For I/O to memory	8 states	667 ns
		01	Word transfer	(DMADn -) \leftarrow (DMASn)		
		10	4-byte transfer	DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		
	010	00	Byte transfer	Transfer source address INC mode For memory to I/O	8 states	667 ns
		01	Word transfer	(DMADn) \leftarrow (DMASn +)		
		10	4-byte transfer	DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		
	011	00	Byte transfer	Transfer source address DEC mode For memory to I/O	8 states	667 ns
		01	Word transfer	(DMADn) \leftarrow (DMASn -)		
		10	4-byte transfer	DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		
	100	00	Byte transfer	Address fixed mode For I/O to I/O	8 states	667 ns
		01	Word transfer	(DMADn) \leftarrow (DMASn)		
		10	4-byte transfer	DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		
	101	00	Counter mode For counting number of times interrupts generated DMASn \leftarrow DMASn + 1 DMACn \leftarrow DMACn - 1 If DMACn = 0, then INTTCn generated		5 states	417 ns

* For external 16-bit bus, 0 waits, word/4-byte transfer mode, transfer source/transfer destination addresses both have even-numbered values.

Note: n: Corresponding micro DMA channels 0 to 3

DMADn + / DMASn + : Post increment (increments register value after transfer)

DMADn - / DMASn - : Post decrement (decrements register value after transfer)

The I/Os in the table mean fixed addresses; memory means incremented and decremented addresses.

Do not use undefined code, that is, codes other than those listed above for the transfer mode register.

3.3.3 Interrupt Controller Control

Figure 3.3.4 is a block diagram of the interrupt controller circuit. The left-hand side of this diagram shows the interrupt controller. The right-hand side shows the CPU interrupt request signal circuit and CPU halt release circuit. (For details on halt modes, see 3.4, Standby Function.)

The interrupt controller has a total of 40 interrupt channels, consisting of NMI, INTWD, INT0 to 8, INTT0 to 7, INTTR8 to 09, INTRX0 to TX1, INTCR to G, INTSE0 to 2, INTAD, and INTTC0 to 3.

Each interrupt channel supports:

- Interrupt request flag (40 channels)
- Interrupt priority setting register (38 channels (NMI and INTWD excluded)).

In addition, there are also four channels of start vector registers for performing micro DMA processing.

(1) Interrupt request flags

The function of the interrupt request flag is to indicate the generation of an interrupt request. Apart from NMI and INTWD, each channel has a clear bit <IxxC> for clearing the interrupt requests (see Figure 3.3.5, Interrupt Priority Setting Registers). Reading clear bit <IxxC> reads the state of the interrupt request flag and indicates whether an interrupt request is generated or not.

The interrupt request flags are zero-cleared by the following operations:

- [1] A reset (clears all interrupt request flags)
- [2] When the CPU accepts an interrupt and reads the vector of the accepted interrupt channel
- [3] When the CPU accepts the micro DMA request of the specified channel
- [4] When 0 is written to clear bit <IxxC> of the interrupt priority setting register

Note: [2], [3], and [4] operations do not include INT0 level mode or INTRX0, 1.

In addition, flags are also cleared by the following operations.

Table 3.3.4 Other Flag Clearing Operations

Flag clearing source		Other operations that clear interrupt flags
Interrupt source		
INT0	Edge mode	Switching to level mode
	Level mode	Change in pin input after interrupt is generated (high level → low level)
INTRX0, 1		Reading serial channel receive buffer

Before clearing an interrupt request by writing 0 to the clear bit or by performing a Table 3.3.4 operation to clear the interrupt request flag, first execute the DI instruction.

(INT0 interrupt cautions)

Note the following cautions when using the INT0 interrupt in level mode.

In level mode, the INT0 pin input must be held continuously at high level until the interrupt response sequence is completed. Likewise, when releasing the halt in this mode, the INT0 pin must be held continuously at high level until the halt is released.

When using INT0 level mode, be sure that a low level is not input as a result of noise as this can cause malfunction.

When switching the INT0 pin operation mode from level to edge mode, first disable the INT0 interrupt as follows. (In level mode, an accepted interrupt request must be cleared.)

Setting example:

```
DI                      ; disable interrupt
LD (IIMC), XX0XXX0XB    ; switch from level to edge
LD (INTE0AD), XXXX0nnnB ; clear interrupt request flag and set INT0
                        ; interrupt level to n
EI                      ; enable interrupt
```

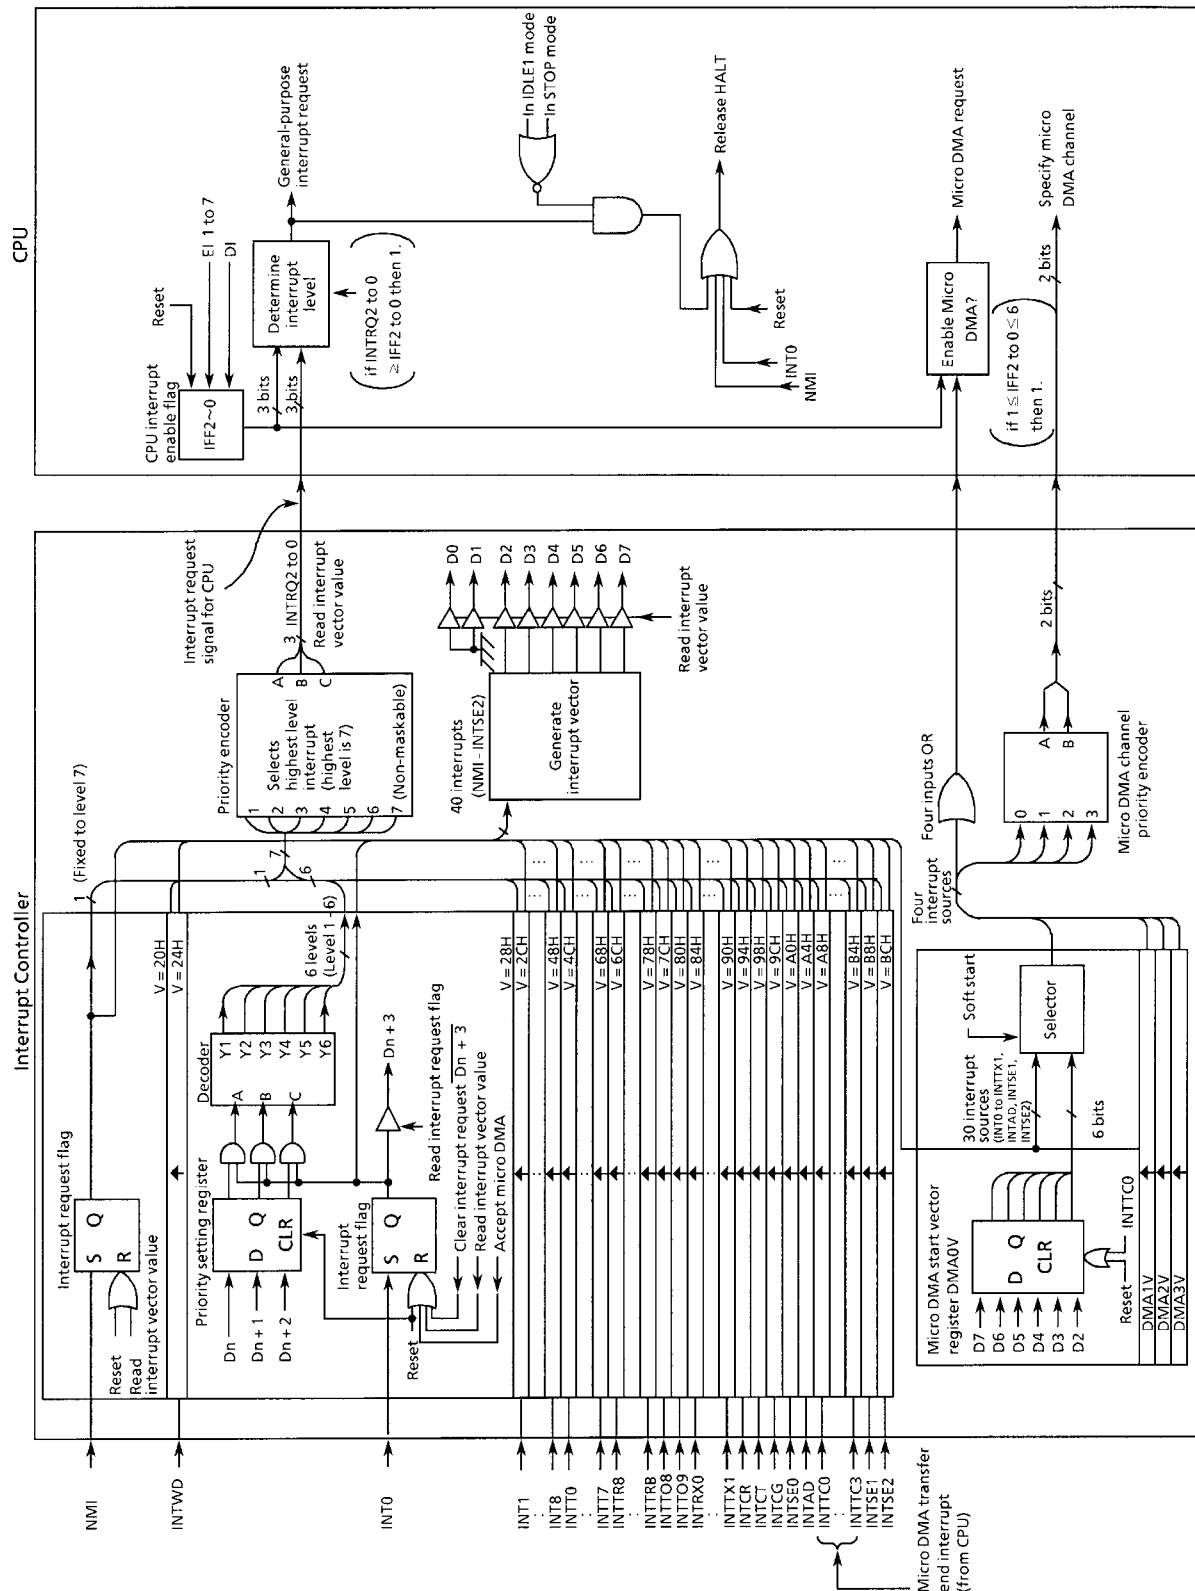

Figure 3.3.4 Block Diagram of Interrupt Controller

(2) Interrupt priority setting register

Figure 3.3.5 shows the interrupt priority setting registers. Each of the 38 interrupt channels (INT0 to AD, INTTC0 to 3, INTSE1, INTSE2) has an interrupt request level setting bit <IxxM2:0>. An interrupt request is generated at six interrupt levels (levels 1 through 6). Setting the priority level to 0 (or 7) disables the corresponding interrupt request. The priority level for non-maskable interrupts ($\overline{\text{NMI}}$ pin input) is fixed to 7. If two or more interrupts with the same level occur simultaneously, the interrupts are accepted in accordance with the default priority.

Symbol	Address	7	6	5	4	3	2	1	0

1	1	0	Sets interrupt priority level to 6
1	1	1	Disables interrupt request

lxxC	Function (Read)	Function (Write)
0	No interrupt request	Clears interrupt request flag
1	Interrupt request	----- Don't care -----

Figure 3.3.5 Interrupt Priority Setting Registers (2/2)

From among simultaneous interrupts, the interrupt controller selects the interrupt request with the highest level and sends its vector address to the CPU.

Then, the CPU compares the priority level of the interrupt request with the value of the interrupt mask register <IFF2:0> in the status register. If the priority level of the interrupt request is higher than the value of the interrupt mask register, the CPU accepts the interrupt. When the CPU side interrupt mask register <IFF2:0> is set to the priority level of the received interrupt incremented by 1, subsequent interrupt requests are only accepted if their level is equal to or greater than the incremented value.

(3) Micro DMA start vector

The interrupt controller has four channels of micro DMA start vector registers. Writing the micro DMA start vector value (Table 3.3.2) for each interrupt source to these registers makes the applicable interrupt request into a micro DMA request. But first set values in the registers for micro DMA parameters (DMAS, DMAD, DMAC, DMAM). Figure 3.3.6 shows the micro DMA start vector registers.

The function of the micro DMA start vector registers is to select the interrupt to use with micro DMA processing. The micro DMA start source is assigned to the interrupt source whose micro DMA start vector matches the vector value set in the micro DMA start vector register.

When the value of the micro DMA transfer counter is set to 0 after micro DMA processing, the CPU generates a micro DMA transfer end interrupt (INTTC0 to 3) corresponding to the micro DMA start vector register. When the micro DMA start vector register is cleared, the micro DMA startup source is released. Therefore, when continuously performing micro DMA processing, set the start vector value in the micro DMA start vector register again during processing of the micro DMA transfer end interrupt.

When the same vector is set in the micro DMA start vector registers of multiple channels, the lower the channel number the higher the priority.

The channel with the lowest number is executed until the micro DMA transfer end interrupt. Unless the micro DMA start vector is set again during the processing of the micro DMA transfer end interrupt, the subsequent micro DMA startup moves to the next smallest channel number. (This operation is called a micro DMA chain.)

INTT 5 interrupt	60H	Micro DMA soft start	FCH
INTT 6 interrupt	64H		

Figure 3.3.6 Setting Micro DMA Start Vector Register and Startup Source

(4) External interrupt control

Table 3.3.5 shows the function settings for the external interrupt pins.

TMP95CU54A can select the operating mode for the $\overline{\text{NMI}}$, INT0, INT5, or INT7 pins from among external interrupt functions. (For details on the external interrupt function pulse width, see “4.7 Interrupt Operations”.)

Table 3.3.5 Setting Functions on External Interrupt Pins

Interrupt pin	Shared pin	Mode	Setting method
$\overline{\text{NMI}}$	—	 Falling edge	IIMC<NMIREE> = 0
		 Both falling and rising edges	IIMC<NMIREE> = 1
INT0	P56	 Rising edge	IIMC<IOLE> = 0, <IOIE> = 1
		 Level	IIMC<IOLE> = 1, <IOIE> = 1
INT1	P70	 Rising edge	—
INT2	P72	 Rising edge	—
INT3	P73	 Rising edge	—
INT4	P75	 Rising edge	—
INT5	P90	 Rising edge	T8MOD<CAP12M1:0> = 0, 0 or 0, 1 or 1, 1
		 Falling edge	T8MOD<CAP12M1:0> = 1, 0
INT6	P91	 Rising edge	—
INT7	P94	 Rising edge	T9MOD<CAP34M1:0> = 0, 0 or 0, 1 or 1, 1
		 Falling edge	T9MOD<CAP34M1:0> = 1, 0
INT8	P95	 Rising edge	—

The input mode of the NMI and INT0 interrupts can be controlled by interrupt input mode control register IIMC.

Figure 3.3.7 shows the interrupt input mode control register.

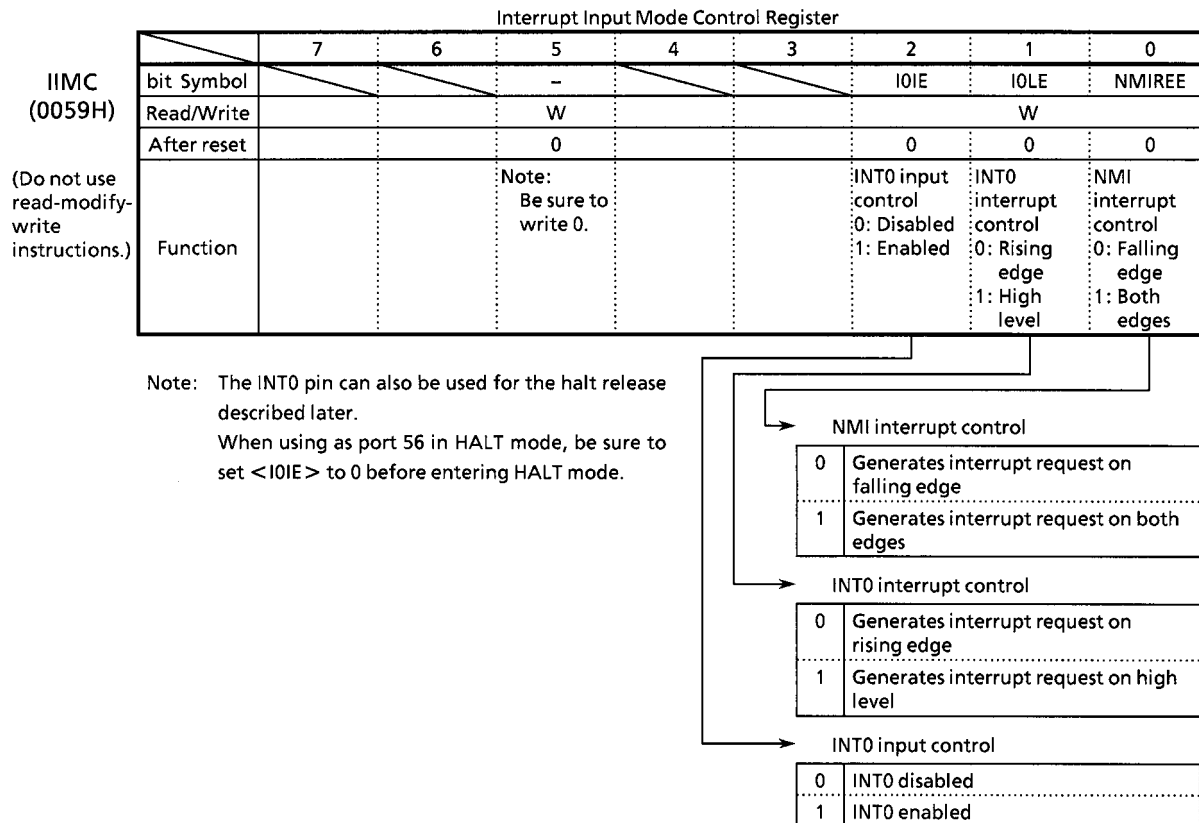

Figure 3.3.7 Interrupt Input Mode Control Register

(5) Caution

When the CPU fetches an instruction to clear the interrupt request flag for the interrupt controller immediately before an interrupt is generated, the CPU may execute the instruction between receiving the interrupt and reading the interrupt vector.

To avoid the above occurring, clear the interrupt request flag by entering the instruction to clear the flag after the DI instruction. When setting an interrupt enable again by EI instruction after the execution of a clearing instruction, execute the EI instruction after the clearing instruction and following the execution of more than one more instruction. If the EI instruction is placed immediately after the clearing instruction, an interrupt could be enabled before interrupt request flags are cleared.

When changing the value of the interrupt mask register<IFF2:0> by execution of a POP SR instruction, disable interrupts by DI instruction before execution of the POP SR instruction.

3.4 Standby Function

(1) HALT modes

When the TMP95CU54A executes a HALT instruction, WDMOD<HALTM1:0> of the watchdog timer mode register can be used to set one of the following HALT modes: RUN, IDLE2, IDLE1, STOP. Figure 3.4.1 shows the watchdog timer mode control register.

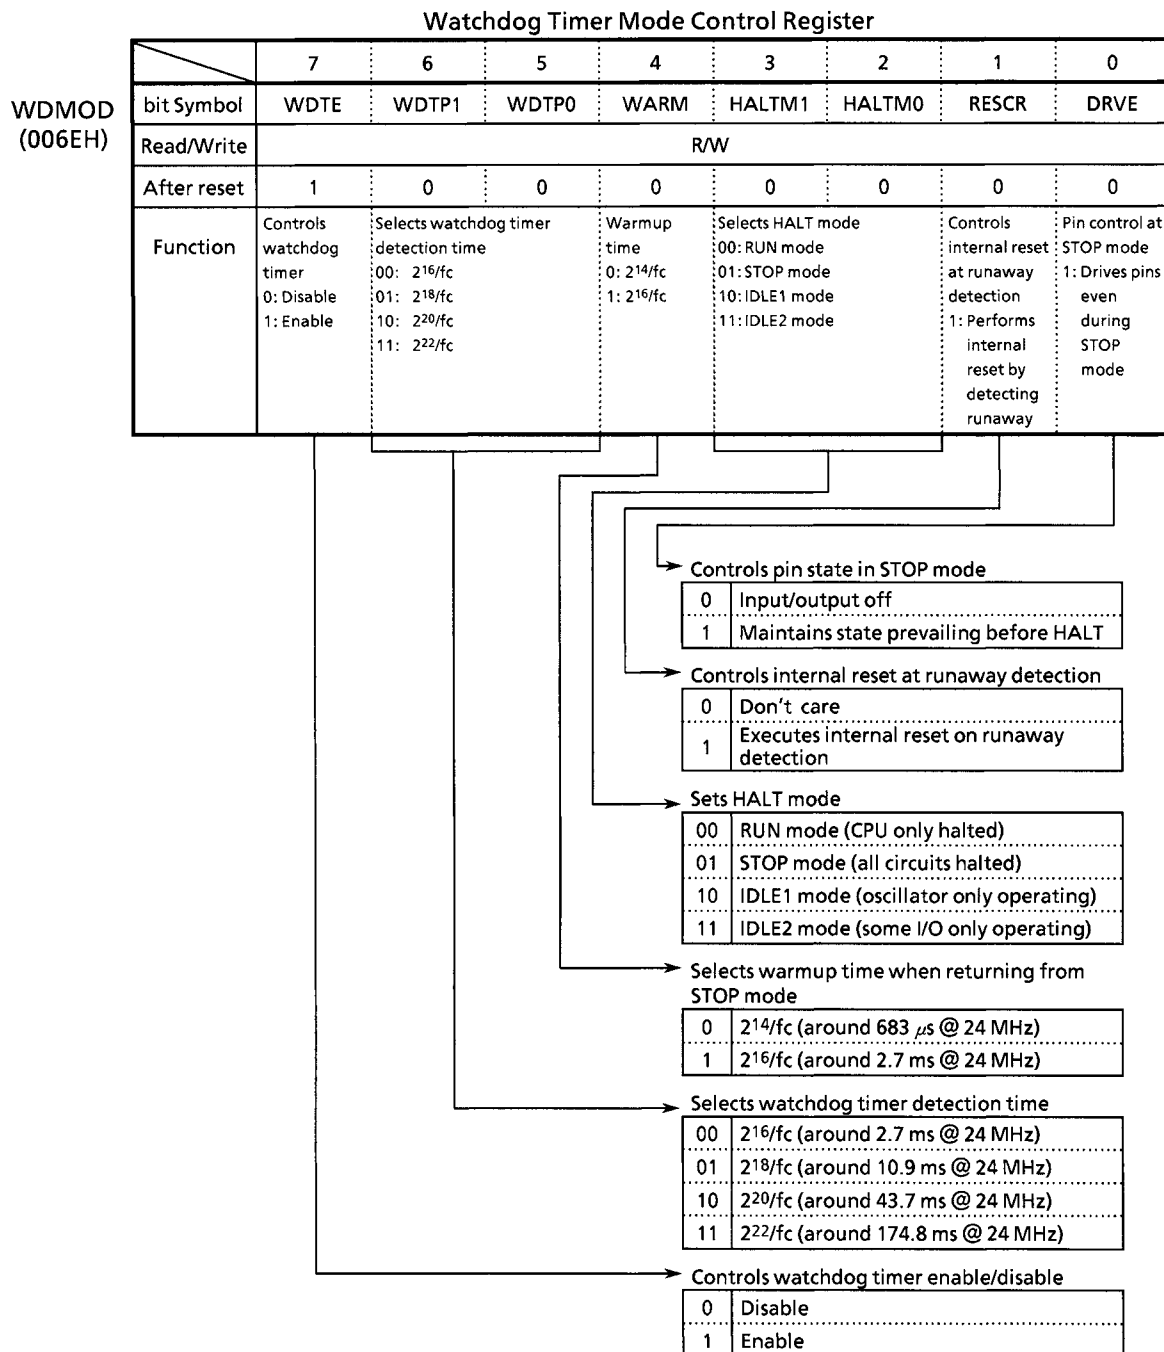

Figure 3.4.1 Watchdog Timer Mode Control Register

The characteristics of RUN, IDLE2, IDLE1, and STOP modes are as follows:

- [1] RUN: In this mode, only the CPU is halted. Power dissipation is almost the same as when the CPU is operating.
- [2] IDLE2: Only the internal oscillator and specific internal I/O operate. Power dissipation is around one half that when the CPU is operating.
- [3] IDLE1: Only the internal oscillator operates; all other circuits are halted. Power dissipation is one tenth of operating mode dissipation.
- [4] STOP: All internal circuits, including the internal oscillator, are halted. In this mode, power dissipation drops considerably.

Table 3.4.1 shows the operation of all blocks in HALT modes.

Table 3.4.1 Blocks and I/O Pin Operation in Halt Modes

Halt mode		RUN	IDLE2	IDLE1	STOP
WDMOD <HALTM1, 0>		00	11	10	01
Operating block	CPU	Halted			
	I/O ports	Maintains state prevailing at HALT instruction execution			See Table 3.4.3
	8-bit timers	<div style="display: flex; align-items: center; justify-content: center;"> <div style="border: 1px solid black; width: 150px; height: 150px; background: repeating-linear-gradient(45deg, transparent, transparent 2px, black 2px, black 4px); margin-right: 20px;"></div> <div style="text-align: center;"> <p>Operating</p> <p>Halted</p> </div> </div>			
	16-bit timers

	Serial expansion				
	CAN controller				
	AD converter				
	Watchdog timer				
	Interrupt controller				

(2) Release from HALT mode

Release from HALT mode can trigger an interrupt request or a reset. A combination of the interrupt mask register <IFF2:0> state and the halt mode determine the useable halt release source. (For details, see Table 3.4.2)

• Release by interrupt request

The operation to release HALT mode by using an interrupt request differs according to the interrupt enable state. If the interrupt request level set prior to the execution of the HALT instruction is higher than the interrupt mask register value, after HALT mode is released, interrupt processing is performed by this source, and processing starts from the next instruction following the HALT instruction. If the interrupt request level is lower than the interrupt mask register value, HALT mode is not released. (At a non-maskable interrupt, interrupt processing is performed after HALT mode release irrespective of the mask register value.)

However, in the case of the INT0 interrupt only, HALT mode can be released if the interrupt request level is lower than the interrupt mask register value. In this case the interrupt processing is not performed. Processing always starts from the next instruction following the HALT instruction. (The INT0 interrupt request flag is held at 1.)

Note: Usually, interrupts can release all halts status. However, the interrupts (= NMI, INT0) which can release the HALT mode may not be able to do so if they are input during the period when the CPU is shifting to the HALT mode (for about 3 clocks of f_c) with IDLE1 or STOP mode (RUN and IDLE2 are not applicable to this case). (In this case, an interrupt request is kept on hold internally)

If another interrupt is generated after it has shifted completely to HALT mode,

halt status can be released without difficulty. The priority of this interrupt is compared with that of the interrupt kept on hold internally, and the interrupt with the higher priority is handled first followed by the other interrupt.

- Release by reset

All HALT modes can be released by a reset. However, when releasing STOP mode, allow sufficient reset time (at least 3ms) for the oscillator to stabilize.

When releasing HALT mode by a reset, the internal RAM retains the data prevailing immediately prior to entering the HALT mode. However, other settings are initialized.

Table 3.4.2 Halt Release Sources and Halt Release Operation

Interrupt accept state			Interrupt enabled (interrupt request level) ≥ (interrupt mask)				Interrupt disabled (interrupt request level) < (interrupt mask)			
HALT mode			RUN	IDLE2	IDLE1	STOP	RUN	IDLE2	IDLE1	STOP
HALT release source	Interrupt source	NMI	□	□	□	□ ^{*1}	—	—	—	—
		INTWD	□	×	×	×	—	—	—	—
		INT0	□	□	□	□ ^{*1}	O	O	O	O ^{*1}
		INT1 to 8	□	□	×	×	×	×	×	×
		INTT0 to 7	□	□	×	×	×	×	×	×
		INTTR8, 9, A, B	□	□	×	×	×	×	×	×
		INTT08, 9	□	□	×	×	×	×	×	×
		INTRX0, TX0	□	□	×	×	×	×	×	×
		INTRX1, TX1	□	□	×	×	×	×	×	×
		INTCR, CT, CG	□	□	×	×	×	×	×	×
		INTSE0, 1, 2	□	□	×	×	×	×	×	×
		INTAD	□	×	×	×	×	×	×	×
	RESET		□	□	□	□	□	□	□	□

□: After HALT mode release, the CPU starts interrupt processing (a reset initializes the LSI).

O: After HALT mode release, processing starts from the next instruction following the HALT instruction.
(No interrupt processing)

×: Not used for HALT release.

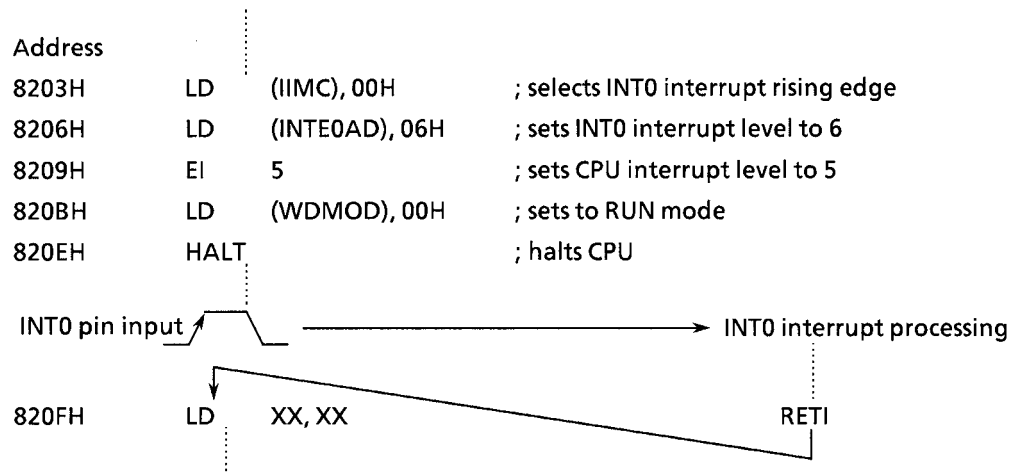

—: As the highest priority level (interrupt request level) for a non-maskable interrupt is fixed to 7, this combination is not available.

*1: Releases HALT after the warmup time has elapsed.

Note: When releasing HALT in an interrupt enabled state by using a level mode INT0 interrupt, maintain high level on pin INT0 until interrupt processing begins. If pin INT0 changes to low level before interrupt processing begins, interrupt processing cannot start correctly.

(Example of release from HALT mode)

Releasing HALT mode using the edge mode INT0 interrupt when the CPU is in RUN mode:

(3) Operation in each mode

[1] RUN mode

In RUN mode, the system clock continues operating even after execution of the HALT instruction. Only the CPU instruction execution operations stop.

In HALT mode, interrupt requests are sampled on the falling edge of the CLK signal.

All the external and internal interrupts can be used for releasing RUN mode. (See Table 3.4.2, Halt Release Sources and Halt Release Operation.)

Figure 3.4.2 shows the timing example for releasing HALT mode using an interrupt.

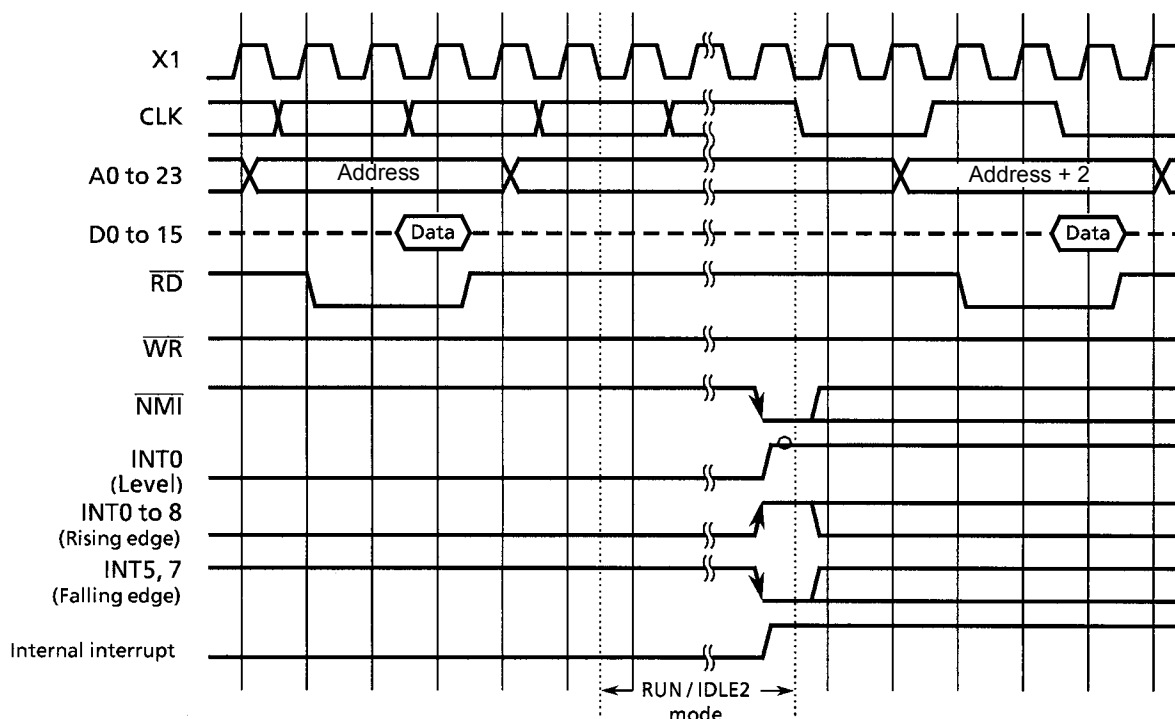

Figure 3.4.2 Example of Timing for Releasing Halt by Interrupt (RUN or IDLE2 Mode)

[2] IDLE2 mode

In IDLE2 mode, the system clock is supplied only to specific internal I/O. CPU instruction execution halts.

In IDLE2 mode, the timing for releasing HALT mode by interrupt is the same as in RUN mode.

External and internal interrupts, apart from INTWD/INTAD, can release IDLE2 mode. (See Table 3.4.2, Halt Release Sources and Halt Release Operation.)

Before entering HALT mode in IDLE2 mode, disable the watchdog timer (to prevent the generation of a watchdog timer interrupt immediately after halt mode release).

[3] IDLE1 mode

In IDLE1 mode, only the internal oscillator operates. The system clock stops. The CLK pin outputs high level.

The interrupt request sampling in HALT mode is asynchronous to the system clock. However, the release (resumption of operation) is synchronous.

Release IDLE1 mode by an external interrupt (NMI, INT0). (See Table 3.4.2, Halt Release Sources and Halt Release Operation.)

Figure 3.4.3 shows the timing example for releasing HALT mode by interrupt.

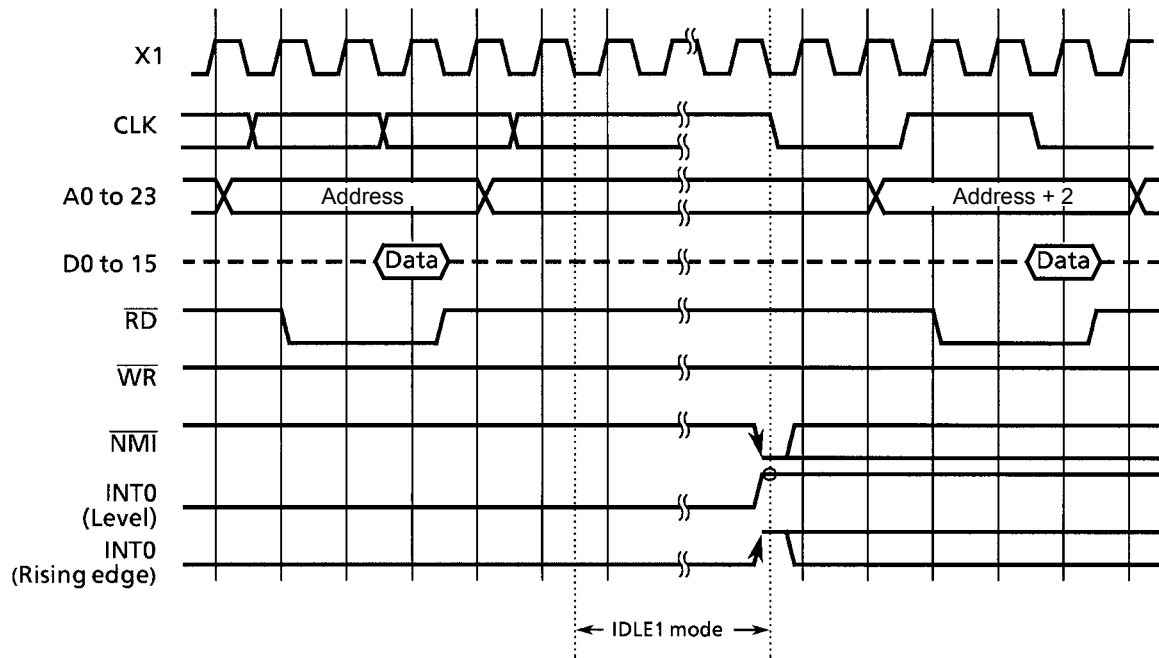

Figure 3.4.3 Example of Timing for Releasing HALT by Interrupt (IDLE1 Mode)

[4] STOP mode

In STOP mode, all internal circuits, including the internal oscillator, are halted. The pin states in STOP mode differ according to the setting of the watchdog timer mode register WDMOD<DRVE>. (For details on the WDMOD<DRVE> settings, see Figure 3.4.1). Table 3.4.3 shows the pin states in STOP mode.

Release STOP mode by an external interrupt (NMI, INT0). When releasing STOP mode, system clock output starts after the elapse of the warmup time (as set in the warmup counter) in order to stabilize the internal oscillator. Set the warmup time in the WDMOD<WARM> register.

Figure 3.4.4 shows an example of the timing for releasing HALT by interrupt.

Figure 3.4.4 Example of Timing for Releasing HALT by Interrupt (STOP Mode)

Table 3.4.3 Pin States in Stop Mode

Pin Name	Input/Output	<DRVE> = 0	<DRVE> = 1
P00 to 07	Input mode Output mode Input/output (D0 to D7)	■ ■ –	■ Output –

P30	Input mode Output mode Output (A8)	PU ■ –	PU Output Output
P31 to 37	Input mode Output mode Output (A9 to A15)	■ ■ –	■ Output Output
P40 to 47	Input mode Output mode Output (A0 to A7)	■ ■ –	■ Output Output
P50 (\overline{RD}), P51 (\overline{WR})	Output mode Output (\overline{RD} , \overline{WR})	■ –	Output High level output
P52 to 55	Input mode Output mode	PU* PU	PU Output
P56 (INT0)	Input mode Output mode Input mode (INT0)	PU PU Input	PU Output Input
P57 (CLKOUT)	Output mode Output (CLKOUT)	PU –	Output High level output
P60 to 63	Input mode Output mode	– –	Input Output
P70 to 75	Input mode Output mode	– –	Input Output
P80, 83, 86	Input mode Output mode	PU* PU*	PU Output
P81, 82, 84, 85, 87	Input mode Output mode	PU* PU	PU Output
P90 to 97	Input mode Output mode	– –	Input Output
PA0 to 7 (AN0 to 7)	Input Input (\overline{ADTRG})	■ –	■ Input
\overline{NMI}	Input	Input	Input
CLK	Output	–	High level output
\overline{RESET}	Input	Input	Input
\overline{EA}	Input	Fixed to High level	Fixed to High level
AM8/16	Input	Fixed to High level	Fixed to High level
X1	Input	–	–
X2	Output	High level	High level

–: Indicates that input is invalid for an input pin or a pin in input mode. Also, that the pin is set to high impedance for an output pin or a pin in output mode.

Input: The input gate is functioning. To prevent the input pin from floating, fix the input voltage to low or high.

Output: Output state

PU: Programmable pull-up pin. The input gate is functioning. Pins without pull-up set must be fixed to prevent through current.

PU*: Programmable pull-up pin. The input gate is disabled. A through current does not occur even if high impedance is set.

■: The input gate continues to operate if the HALT instruction is executed and the CPU is halted at the port register address value. To prevent a through current in this case, either fix the pin or ensure by software that the situation does not occur. In other cases, input is invalid.

X: Cannot be used.

Note: The port register controls the programmable pull-up. However, if the function is set for a pin shared with an output function (eg, TxD0), the pull-up selection for the pin depends on the output function data. For pins that are shared with input functions, the port register setting alone determines whether or not a pull-up resistor is used.

3.5 Port Functions

TMP95CU54A has a total of 81 bits for input/output ports.

As well as being used as general-purpose I/O ports, port pins are also used for internal CPU and built-in I/O functions. Table 3.5.1 lists port pin functions; Table 3.5.2, pin settings.

Table 3.5.1 Port Pin Functions

Port Name	Pin Name	Number of Pins	Direction	R	Direction Setting Unit	Pin Name for Built-In Function
Port 0	P00 to P07	8	Input/output	—	Bit	D0 to D7
Port 1	P10 to P17	8	Input/output	—	Bit	D8 to D15
Port 2	P20 to P27	8	Input/output	—	Bit	A16 to A23
Port 3	P30	1	Input/output	↑	Bit	A8
	P31 to P37	7	Input/output	—	Bit	A9 to A15
Port 4	P40 to P47	8	Input/output	—	Bit	A0 to A7
Port 5	P50	1	Output	—	(Fixed)	RD
	P51	1	Output	—	(Fixed)	WR
	P52	1	Input/output	↑	Bit	HWR
	P53	1	Input/output	↑	Bit	BUSRQ
	P54	1	Input/output	↑	Bit	BUSAK
	P55	1	Input/output	↑	Bit	WAIT
	P56	1	Input/output	↑	Bit	INT0
	P57	1	Output	↑	(Fixed)	CLKOUT
Port 6	P60	1	Input/output	—	Bit	SS
	P61	1	Input/output	—	Bit	MOSI
	P62	1	Input/output	—	Bit	MISO
	P63	1	Input/output	—	Bit	SCLK
Port 7	P70	1	Input/output	—	Bit	TI0/INT1
	P71	1	Input/output	—	Bit	TO1
	P72	1	Input/output	—	Bit	TO3/INT2
	P73	1	Input/output	—	Bit	TI3/INT3
	P74	1	Input/output	—	Bit	TO5
	P75	1	Input/output	—	Bit	TO7/INT4
Port 8	P80	1	Input/output	↑	Bit	TxD0
	P81	1	Input/output	↑	Bit	RxD0
	P82	1	Input/output	↑	Bit	SCLK0/CTS0
	P83	1	Input/output	↑	Bit	TxD1
	P84	1	Input/output	↑	Bit	RxD1
	P85	1	Input/output	↑	Bit	SCLK1/CTS1
	P86	1	Input/output	↑	Bit	Tx
	P87	1	Input/output	↑	Bit	Rx
Port 9	P90	1	Input/output	—	Bit	TI8/INT5
	P91	1	Input/output	—	Bit	TI9/INT6
	P92	1	Input/output	—	Bit	TO8
	P93	1	Input/output	—	Bit	TO9
	P94	1	Input/output	—	Bit	TIA/INT7
	P95	1	Input/output	—	Bit	TIB/INT8
	P96	1	Input/output	—	Bit	TOA/TOB
Port A	PA0 to PA2	3	Input	—	(Fixed)	AN0 to AN2
	PA3	1	Input	—	(Fixed)	AN3 / ADTRG
	PA4 to PA7	4	Input	—	(Fixed)	AN4 to AN7

R: ↑ = With programmable pull-up resistor

Note: P30 is pulled-up during reset and input mode.

P57 is pulled-up only during reset.

Table 3.5.2 Port Pin Setting Methods (1/3)

n: Corresponding port no. X: Don't care

Port Name	Pin Name	Function	Port Register Setting		
			Pn	PnCR	PnFC
Port 0	P00 to P07	Input port	X	0	None

		TO8 output	X	1	1
	P93	Input port	X	0	X
		Output port	X	1	0
		TO9 output	X	1	1
	P94	Input port/TIA/INT7 input	X	0	None
		Output port	X	1	
	P95	Input port/TIB/INT8 input	X	0	
		Output port	X	1	
	P96	TOA/TOB output (Note 3)	X	1	1
Port A	PA0 to PA7	Input port	X	None	
		AN0 to AN7 input (Note 4)	X		

Note 3: P9FC<TOS1> is used to switch between the TOA and TOB timer outputs to pin P96.

Note 4: When PA0 to PA7 are used as AD converter input channels, AD mode control register 1 ADMOD1<ADCH2:0> is used to select the channel.

3.5.1 Port 0 (P00 to P07)

Port 0 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 0 also functions as the data bus (D0 to D7). The port 0 control register P0CR sets the pins as inputs or outputs.

A reset sets all the bits of the P0CR register to 0, and sets all pins to input mode.

When external memory is accessed, the port automatically functions as the data bus (D0 to D7) and all bits of P0CR are cleared to 0.

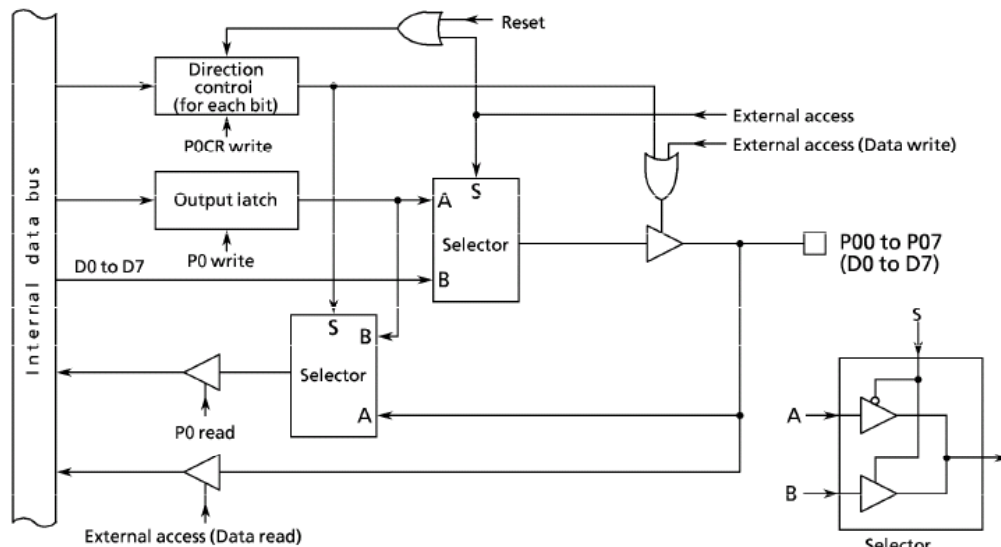

Figure 3.5.1 Port 0 (P00 to P07)

		Port 0 Register							
P0 (0000H)		7	6	5	4	3	2	1	0
	bit Symbol	P07	P06	P05	P04	P03	P02	P01	P00
	Read/Write	R/W							
	After reset	Input mode (output latch register undefined)							
	Function	Also functions as D7 to D0							

		Port 0 Control Register							
		7	6	5	4	3	2	1	0
P0CR (0002H)	bit Symbol	P07C	P06C	P05C	P04C	P03C	P02C	P01C	P00C
	Read/Write	W							
	After reset	0	0	0	0	0	0	0	0
	Function	Port 0 input/output settings 0: Input 1: Output							

Note: When functioning as a data bus (D0 to D7), P0CR is cleared to 0.

Figure 3.5.2 Register for Port 0

3.5.2 Port 1 (P10 to P17)

Port 1 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 1 also functions as a data bus (D8 to D15). The port 1 control register P1CR and function register P1FC set the port 1 functions.

Reset sets all the bits of the P1 output latch register and all bits of the P1CR and P1FC registers to 0, and sets port 1 to input mode.

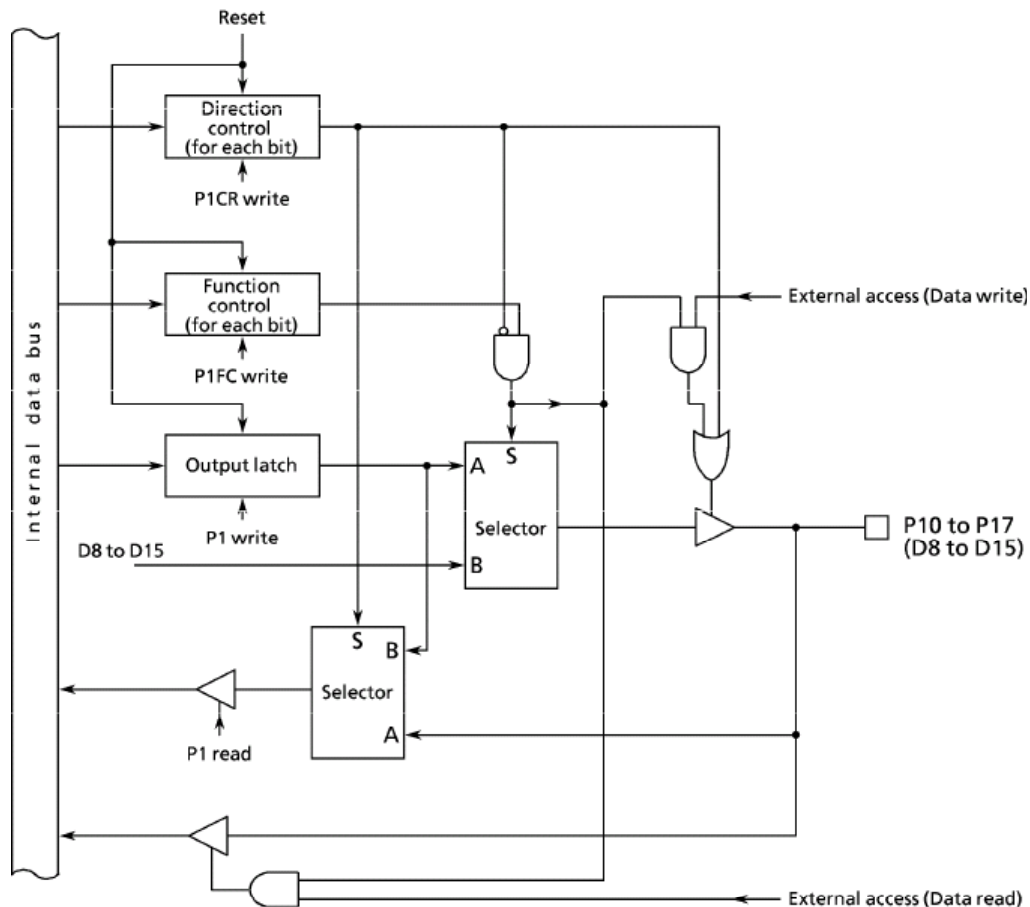

Figure 3.5.3 Port 1 (P10 to P17)

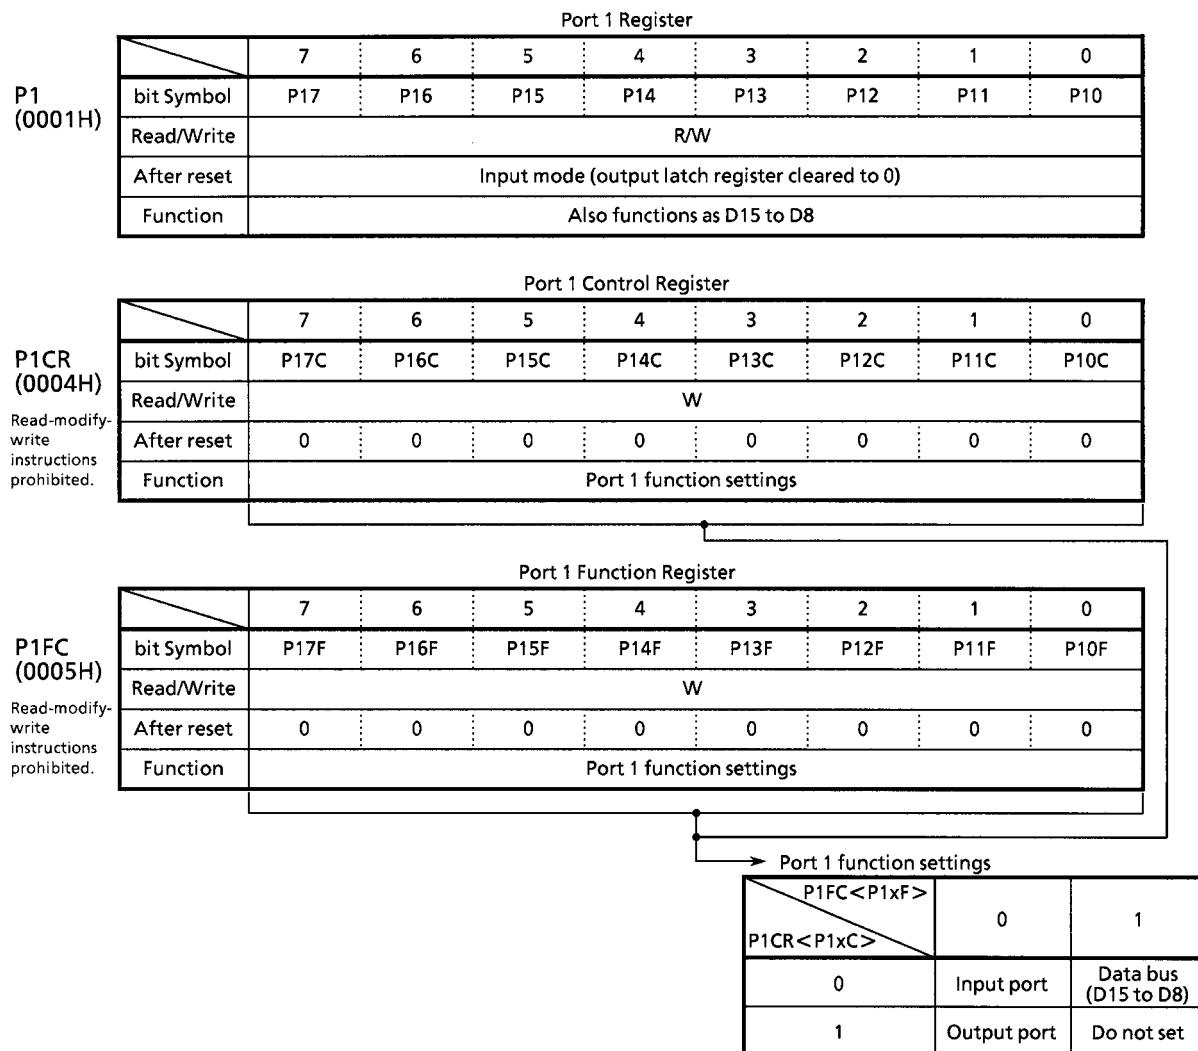

Figure 3.5.4 Register for Port 1

3.5.3 Port 2 (P20 to P27)

Port 2 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 2 also functions as an address bus (A16 to A23). The port 2 control register P2CR and function register P2FC set the port 2 functions.

Reset sets all the bits of the P2 output latch register and all bits of the P2CR and P2FC registers to 0, setting port 2 to input mode.

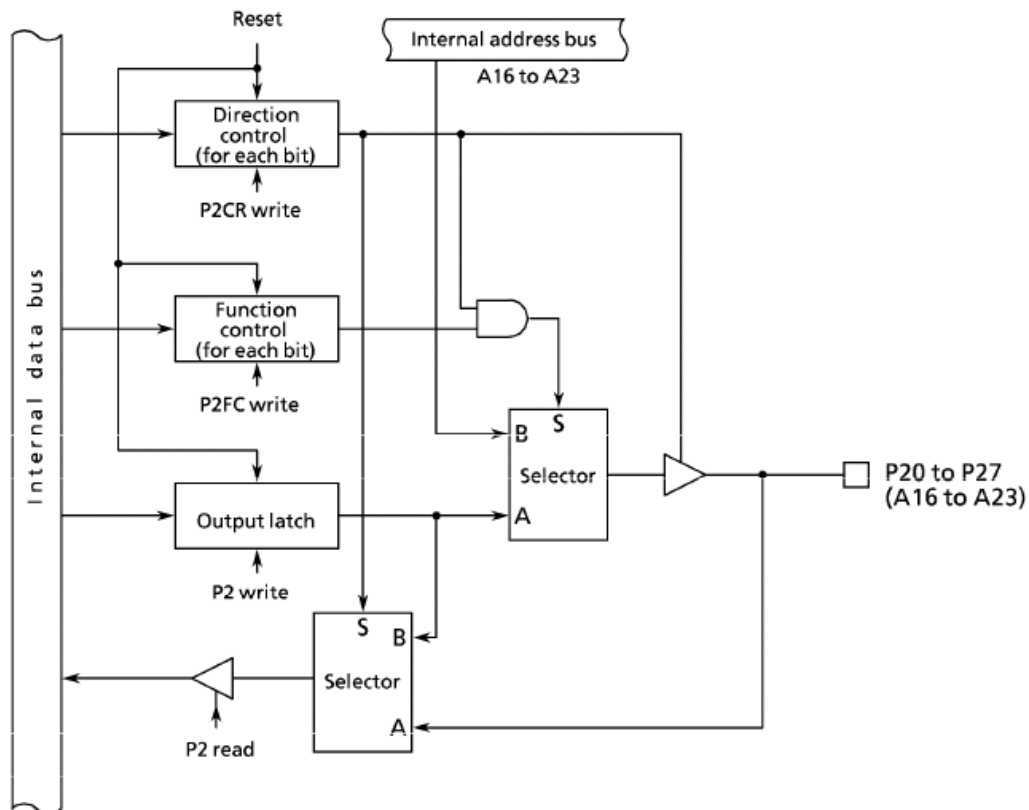

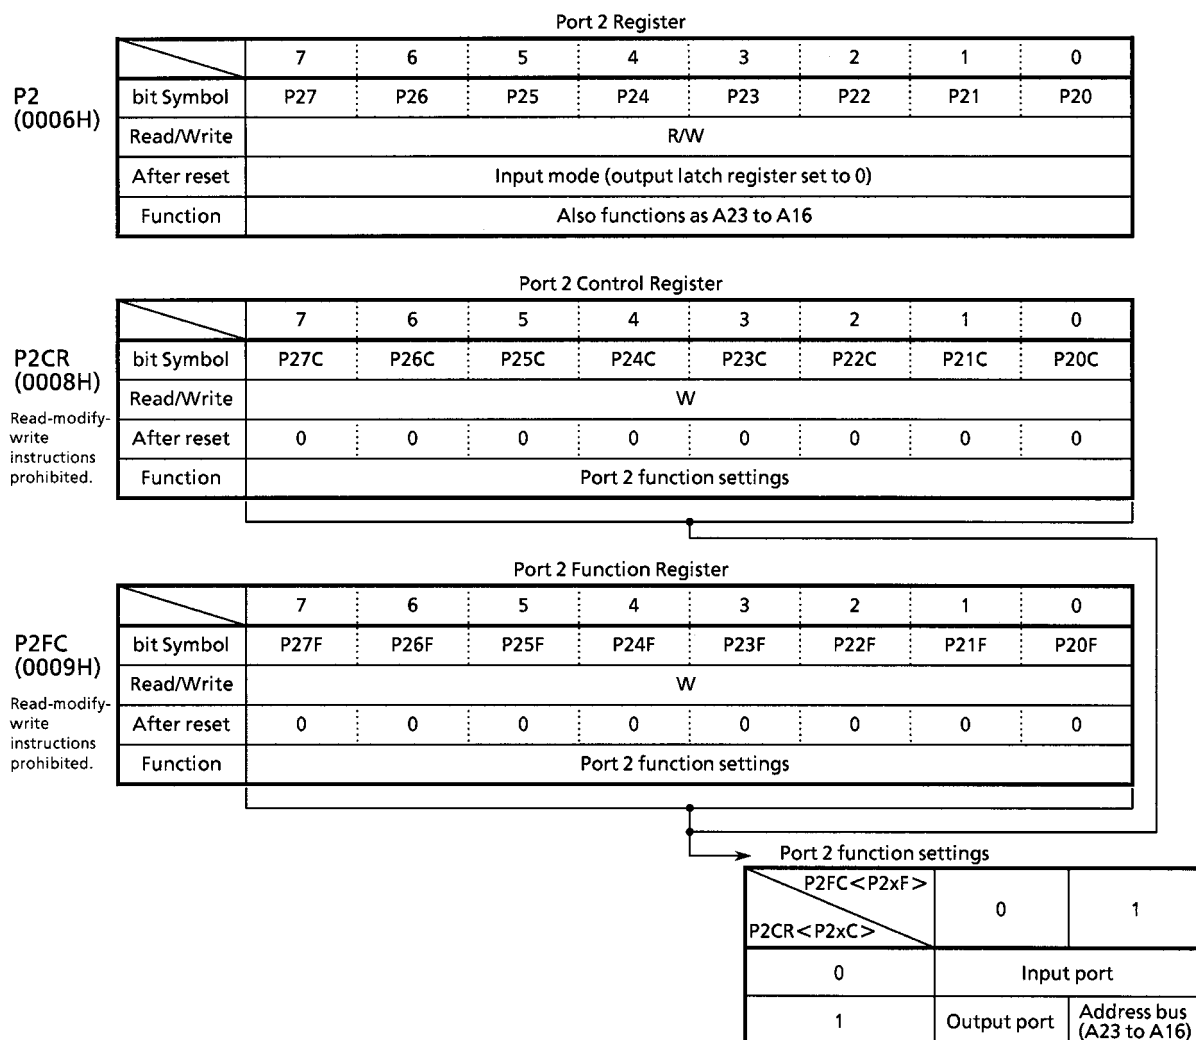

Figure 3.5.5 Port 2 (P20 to P27)

Note: When setting the address bus (A23 to A16), first set P2CR, then P2FC.

Figure 3.5.6 Register for Port 2

3.5.4 Port 3 (P30 to P37)

Port 3 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 3 also functions as an address bus (A8 to A15). The port 3 control register P3CR and function register P3FC set the port 3 functions.

Reset sets all the bits of the P3 output latch register and all bits of the P3CR and P3FC registers to 0. Pin P30 is set to input mode with pull-up; P31 to P37 are set to input mode.

(1) Port 30 (A8)

In addition to being a general-purpose input/output port, port 30 also functions as an address bus (A8).

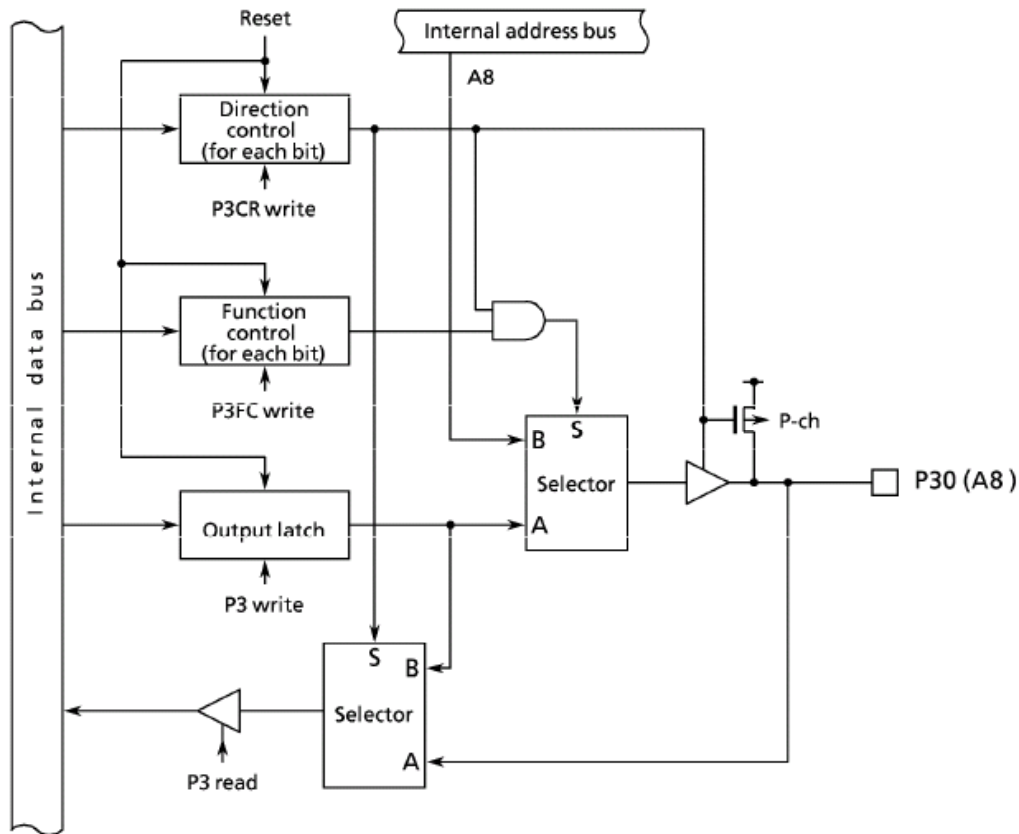

Figure 3.5.7 Port 3 (P30)

(2) Port 31 to 37 (A9 to A15)

In addition to functioning as a general-purpose input/output port, port 31 to 37 also functions as an address bus (A9 to A15).

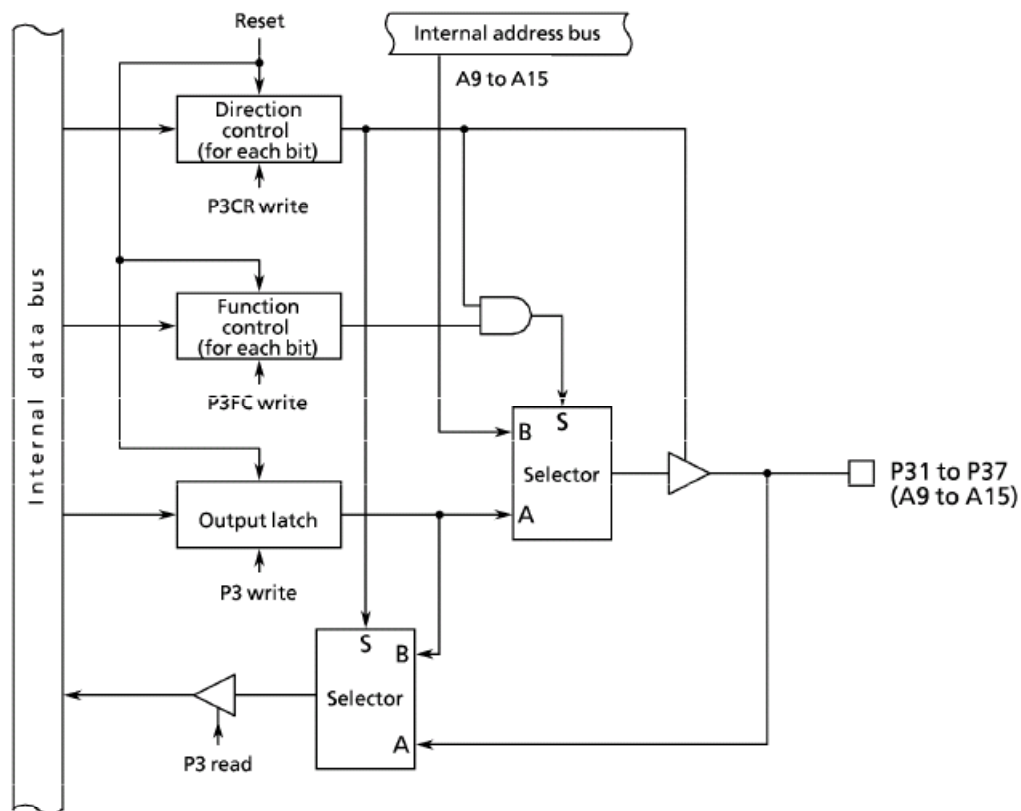

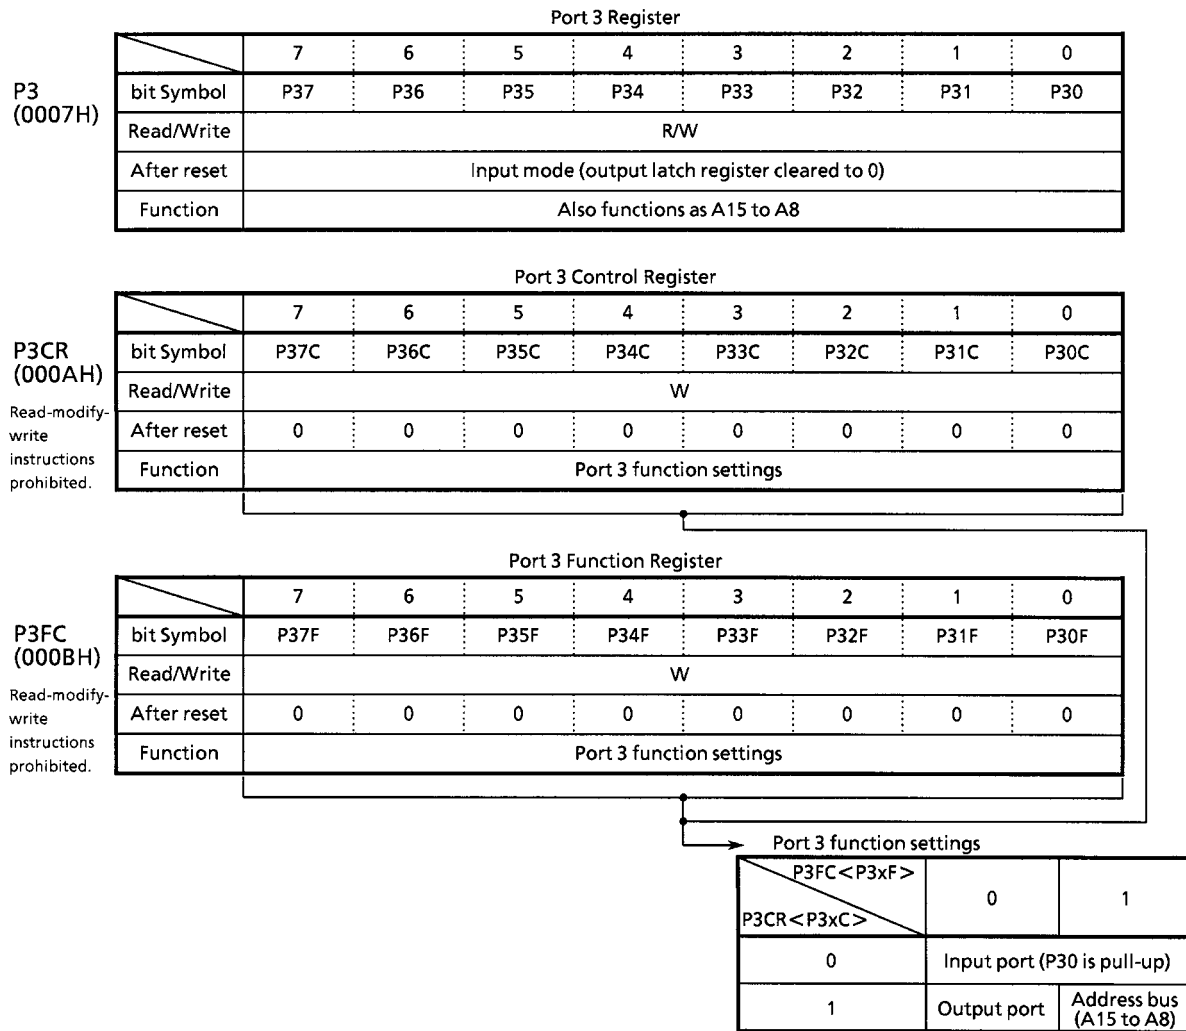

Figure 3.5.8 Port 3 (P31 to P37)

Note: When setting the address bus (A15 to A8), first set P3CR, then P3FC.

Figure 3.5.9 Register for Port 3

3.5.5 Port 4 (P40 to P47)

Port 4 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 4 also functions as an address bus (A0 to A7). The port 4 control register P4CR and function register P4FC set the port 4 functions.

Reset sets all the bits of the P4 output latch register and all bits of the P4CR and P4FC registers to 0, setting port 4 to input mode.

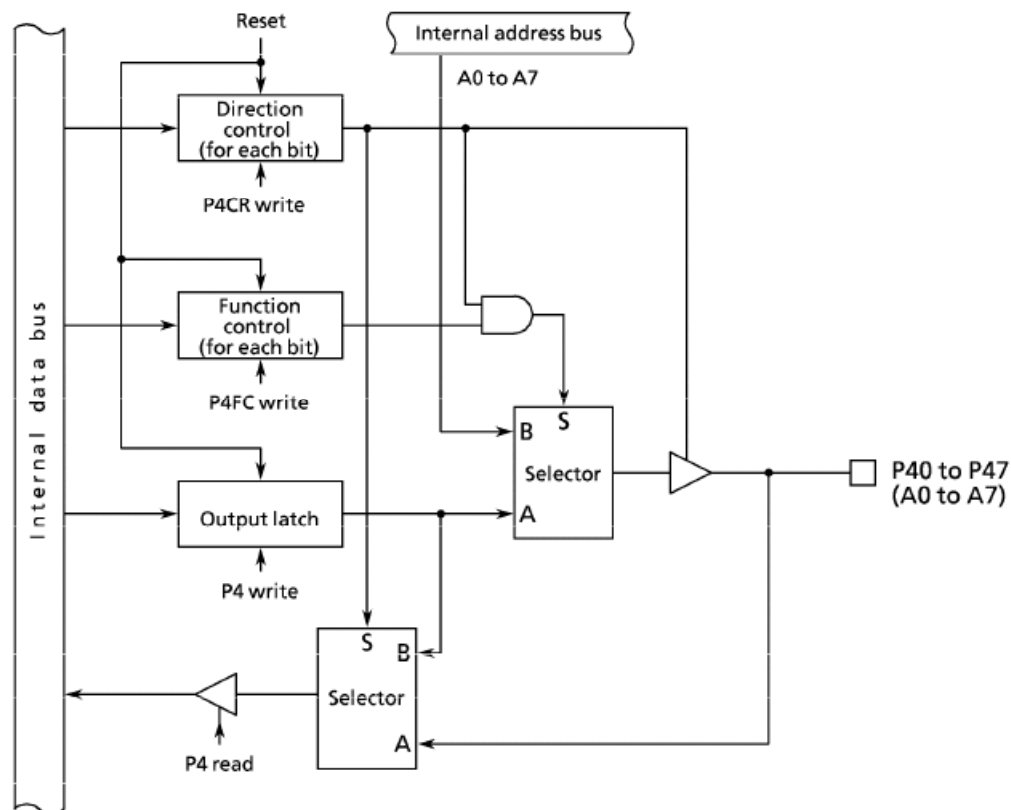

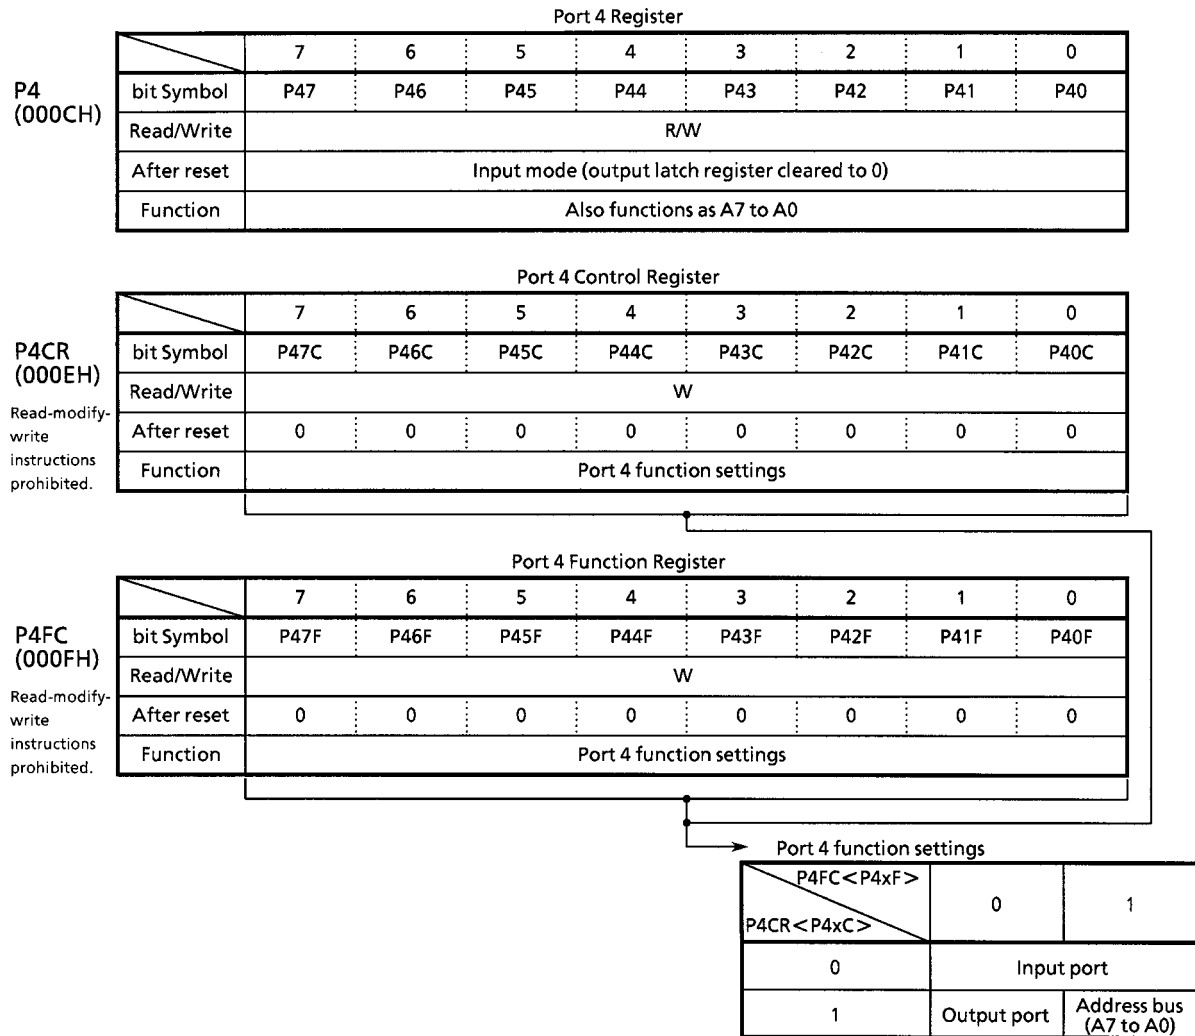

Figure 3.5.10 Port 4 (P40 to P47)

Note: When setting the address bus (A7 to A0), first set P4CR, then P4FC.

Figure 3.5.11 Register for Port 4

3.5.6 Port 5 (P50 to P57)

Port 5 is an 8-bit general-purpose input/output port with each port bit settable as an input or output. However, P50, P51 and P57 are output-only ports.

In addition to functioning as a general-purpose input/output port, port 5 also has a CPU control/status signal input/output function, a $\overline{\text{WAIT}}$ input function, an INT0 external interrupt input function, and a CLKOUT output function. The port 5 control register P5CR and function register P5FC set the port 5 functions.

Reset sets all the bits of the P5 output latch register and bit 7 of P5FC to 1 and clears all bits of P5CR (bits 0, 1 and 7 are unused) and bits 0, 1, 2, 3 and 4 of P5FC (bits 5 and 6 are unused) to 0. Pins P50 and P51 output 1 and P52 to P56 are set to input mode with resistors pulled up and P57 output CLKOUT.

When P50 is set as the $\overline{\text{RD}}$ pin (when $\text{P5FC} \langle \text{P50F} \rangle = 1$) when $\text{P5} \langle \text{P50} \rangle$ is cleared to 0, the P50 $\overline{\text{RD}}$ signal is output even when an internal address area is accessed, and external PSRAM (pseudo SRAM) can be refreshed. If $\langle \text{P50} \rangle$ is set to 1, the $\overline{\text{RD}}$ signal is output only when an external area is accessed.

(1) Port 50 ($\overline{\text{RD}}$)

In addition to functioning as a general-purpose output-only port, port 50 can also function as the $\overline{\text{RD}}$ pin.

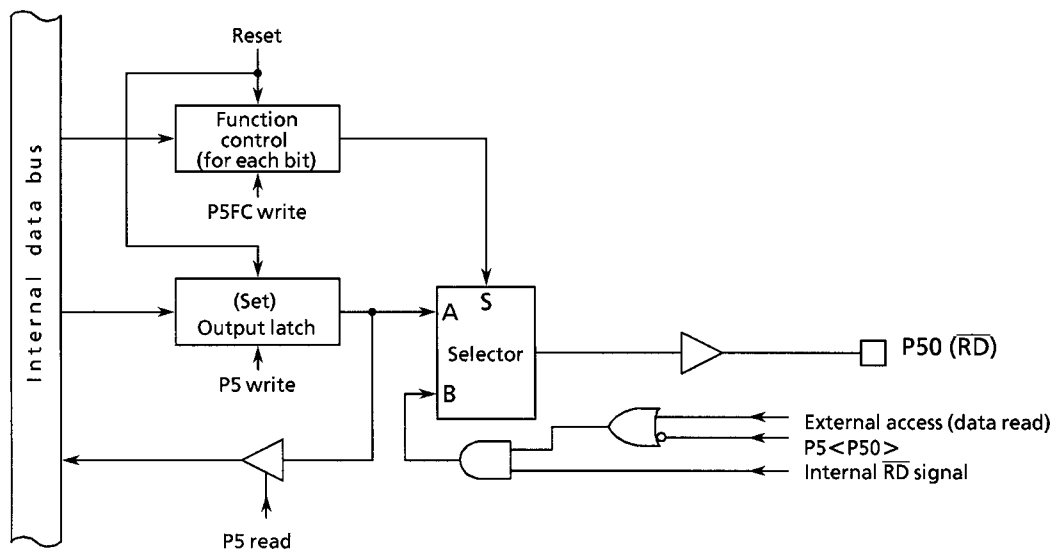

Figure 3.5.12 Port 5 (P50)

(2) Port 51 (\overline{WR})

In addition to functioning as a general-purpose output-only port, port 51 can also function as the \overline{WR} pin.

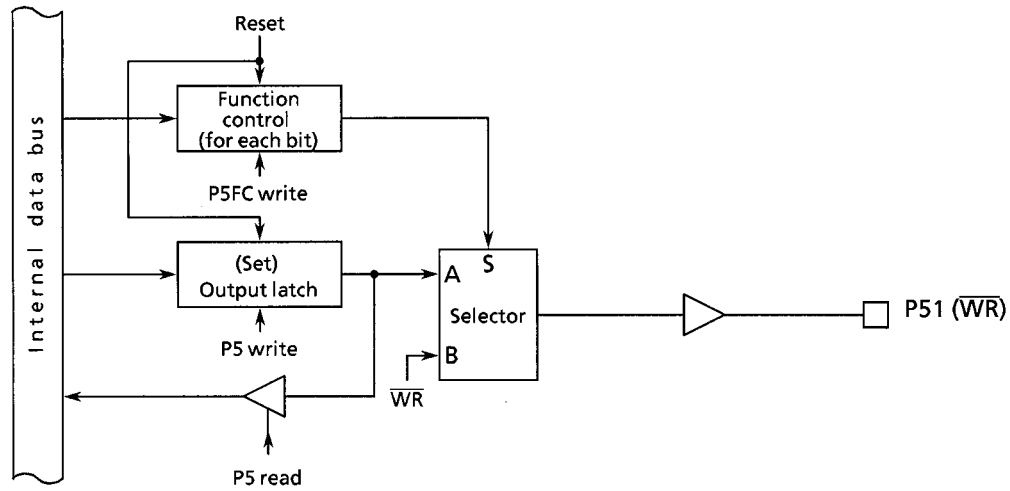

Figure 3.5.13 Port 5 (P51)

(3) Ports 52, 54 (\overline{HWR} , \overline{BUSAK})

In addition to being general-purpose input/output ports, port 52 can also function as the \overline{HWR} pin, and port 54 can also function as the \overline{BUSAK} pin.

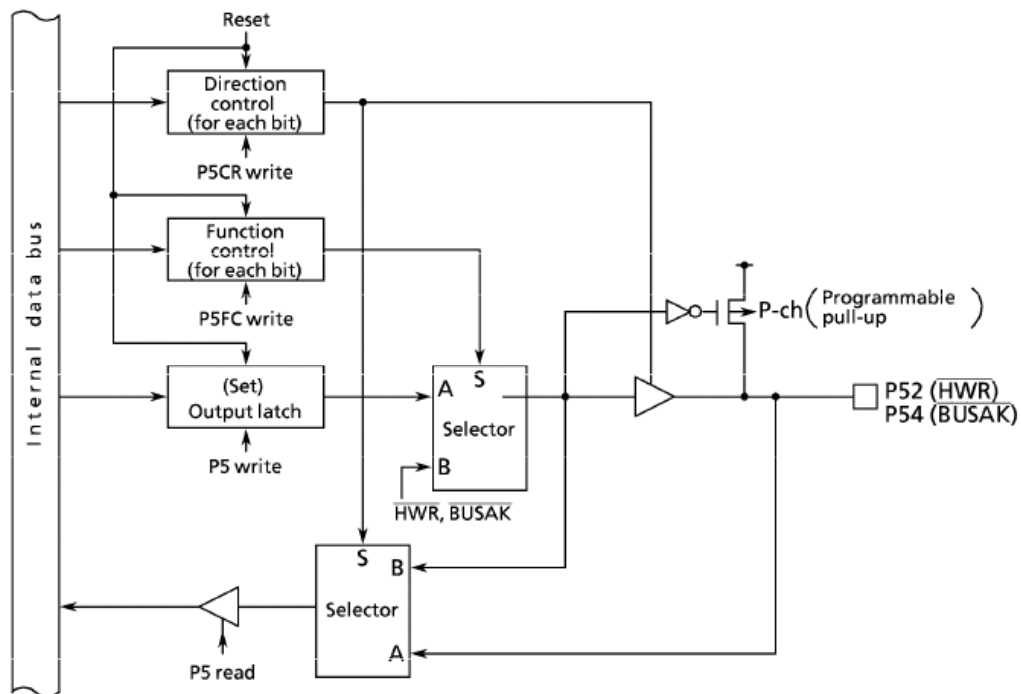

Figure 3.5.14 Port 5 (P52, P54)

(4) Port 53 ($\overline{\text{BUSRQ}}$)

In addition to being a general-purpose input/output port, port 53 also functions as the $\overline{\text{BUSRQ}}$ pin.

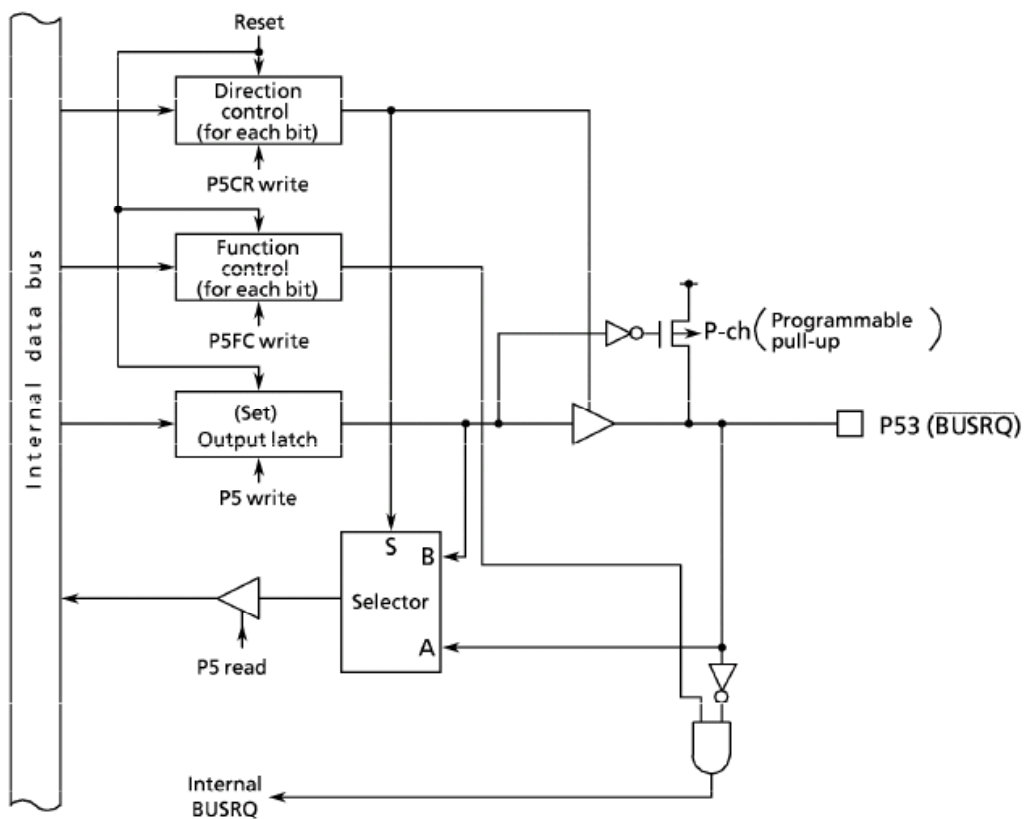

Figure 3.5.15 Port 5 (P53)

(5) Port 55 ($\overline{\text{WAIT}}$)

In addition to being a general-purpose input/output port, port 55 also functions as the $\overline{\text{WAIT}}$ pin.

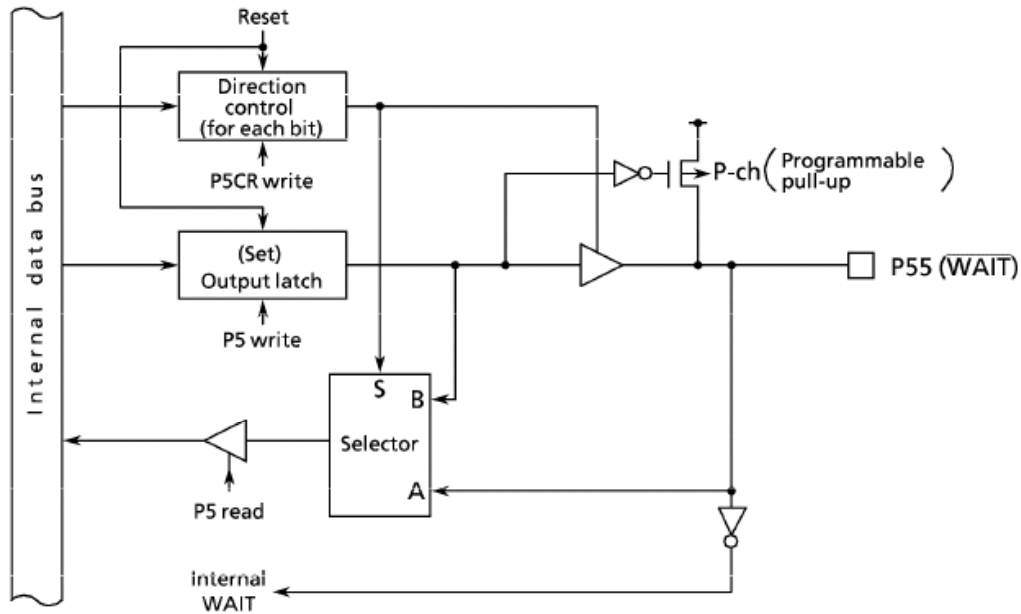

Figure 3.5.16 Port 5 (P55)

(6) Port 56 (INT0)

In addition to being a general-purpose input/output port, port 56 also functions as the external interrupt request input INT0 pin.

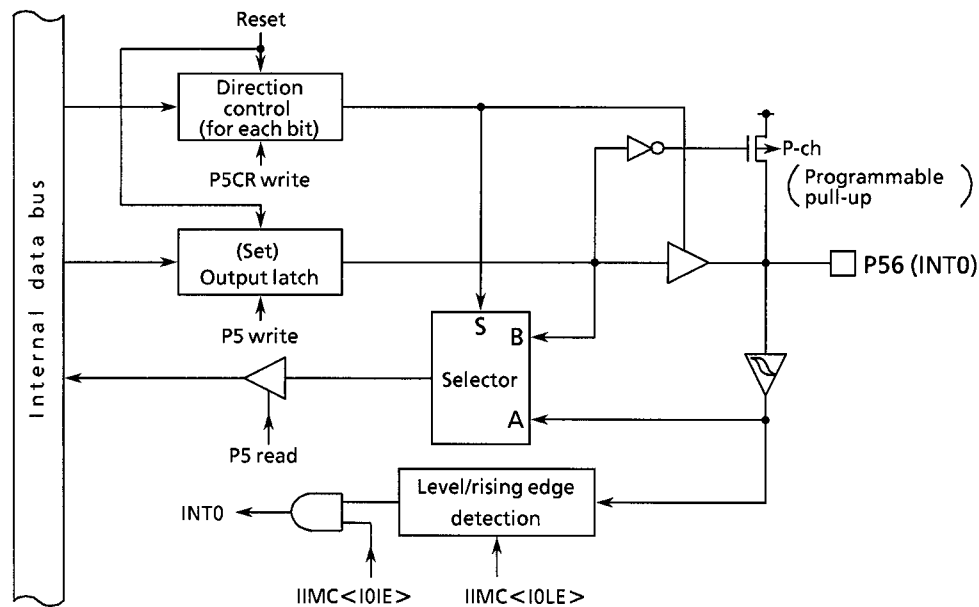

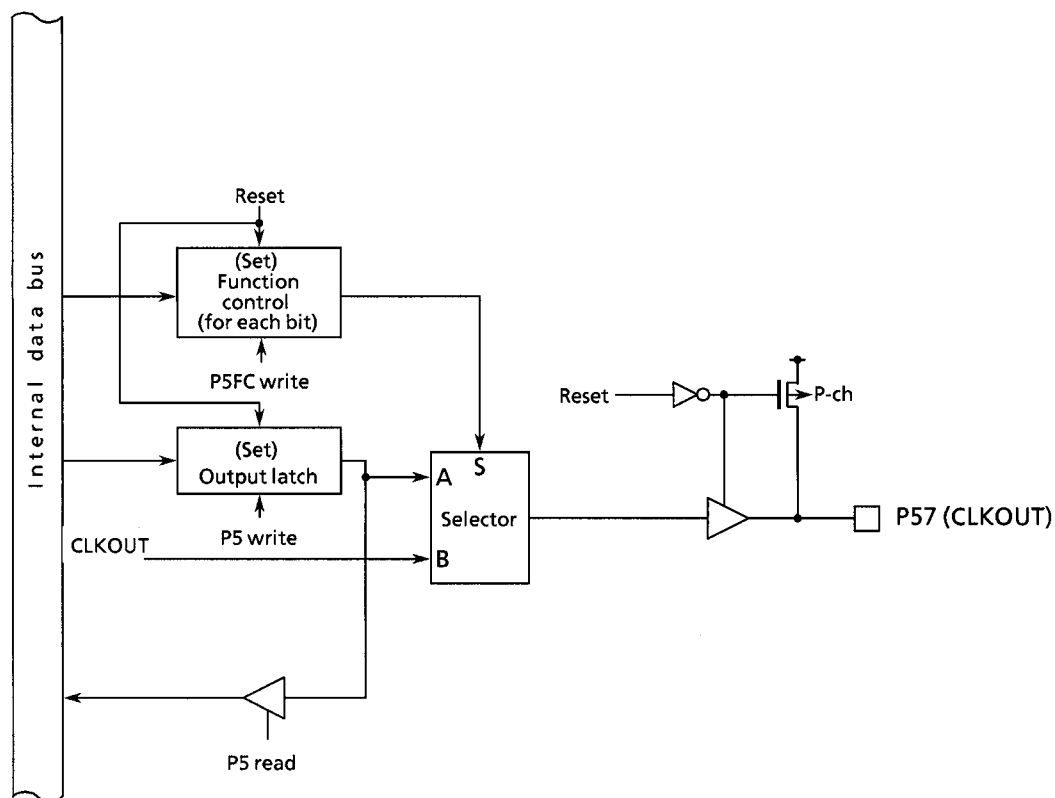

Figure 3.5.17 Port 5 (P56)

(7) Port 57 (CLKOUT)

In addition to being a general-purpose output port, port 57 also functions as the CLKOUT output pin.

Note: During the reset, port 57 is pulled up. After the reset, port 57 functions as the CLKOUT output pin.

Figure 3.5.18 Port 5 (P57)

Port 5 Register								
	7	6	5	4	3	2	1	0
bit Symbol	P57	P56	P55	P54	P53	P52	P51	P50
P5 (000DH)	Read/Write							
After reset	Output only (set to 1)	Input mode (Set to 1 / pulled up)					Output only (set to 1)	
Function	Also functions as CLKOUT	Also functions as INT0	Also functions as WAIT	Also functions as BUSAK	Also functions as BUSRQ	Also functions as HWR	Also functions as WR	Also functions as RD

Note: When port 5 is in input mode, the internal pull-up resistor is controlled by the P5 register. When using port 5 in input mode or in both input and output modes (if just one bit is set to input mode), read-modify-write instructions cannot be executed. The internal pull-up resistor setting may change depending on the state of the input pin.

Port 5 Control Register

Note 1: When using port 55 as the $\overline{\text{WAIT}}$ pin, set P5CR<P55C> to 0 and set the bus width/wait control register WAITCx<BxW2:0> to 010 (1 WAIT + N) or 100 (0 + N WAIT).

Note 2: When using port 56 as the INT0 pin, set P5CR<P56C> to 0 and set the interrupt input mode control register IIMC<IOIE> to 1.

Figure 3.5.19 Register for Port 5 (1/2)

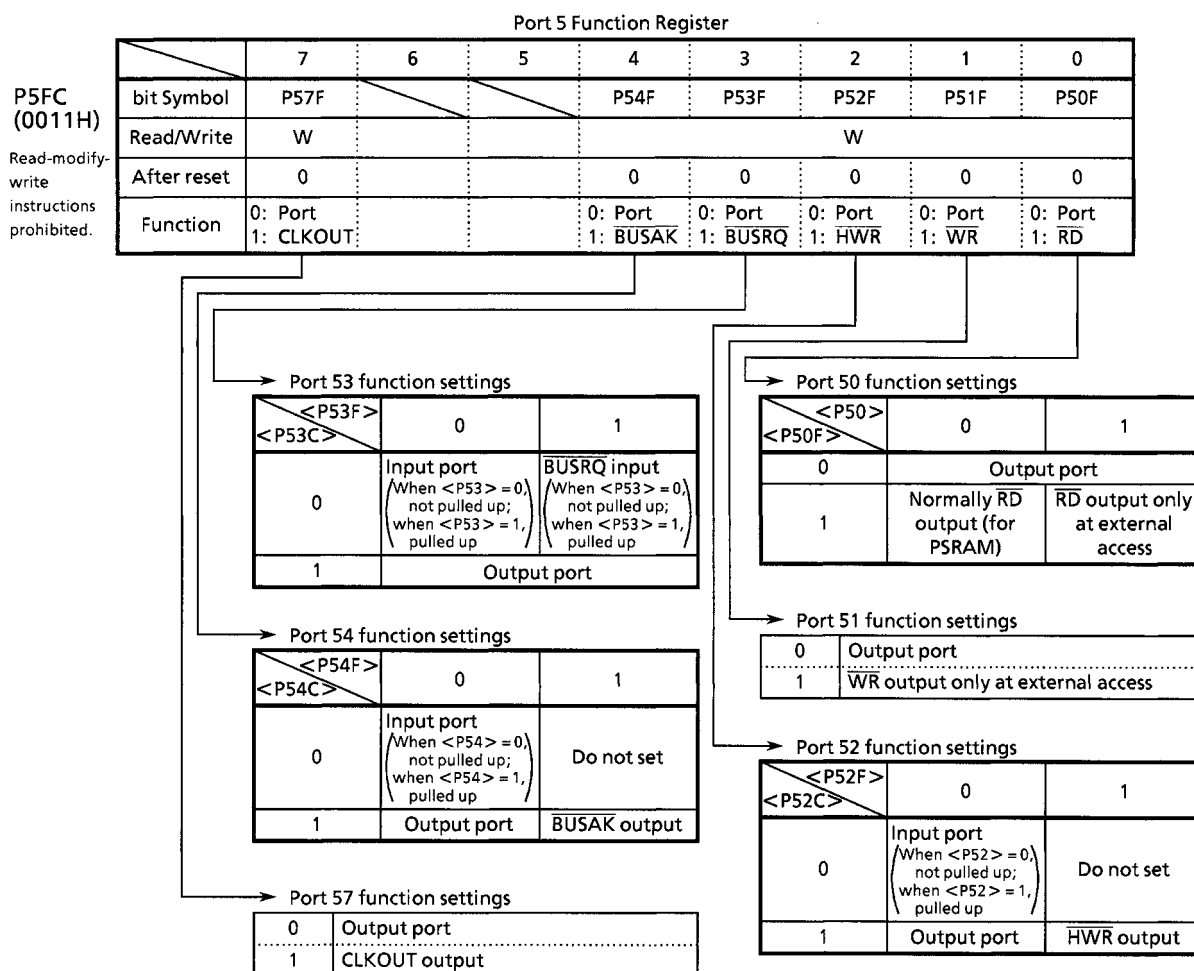

Figure 3.5.19 Register for Port 5 (2/2)

3.5.7 Port 6 (P60 to P63)

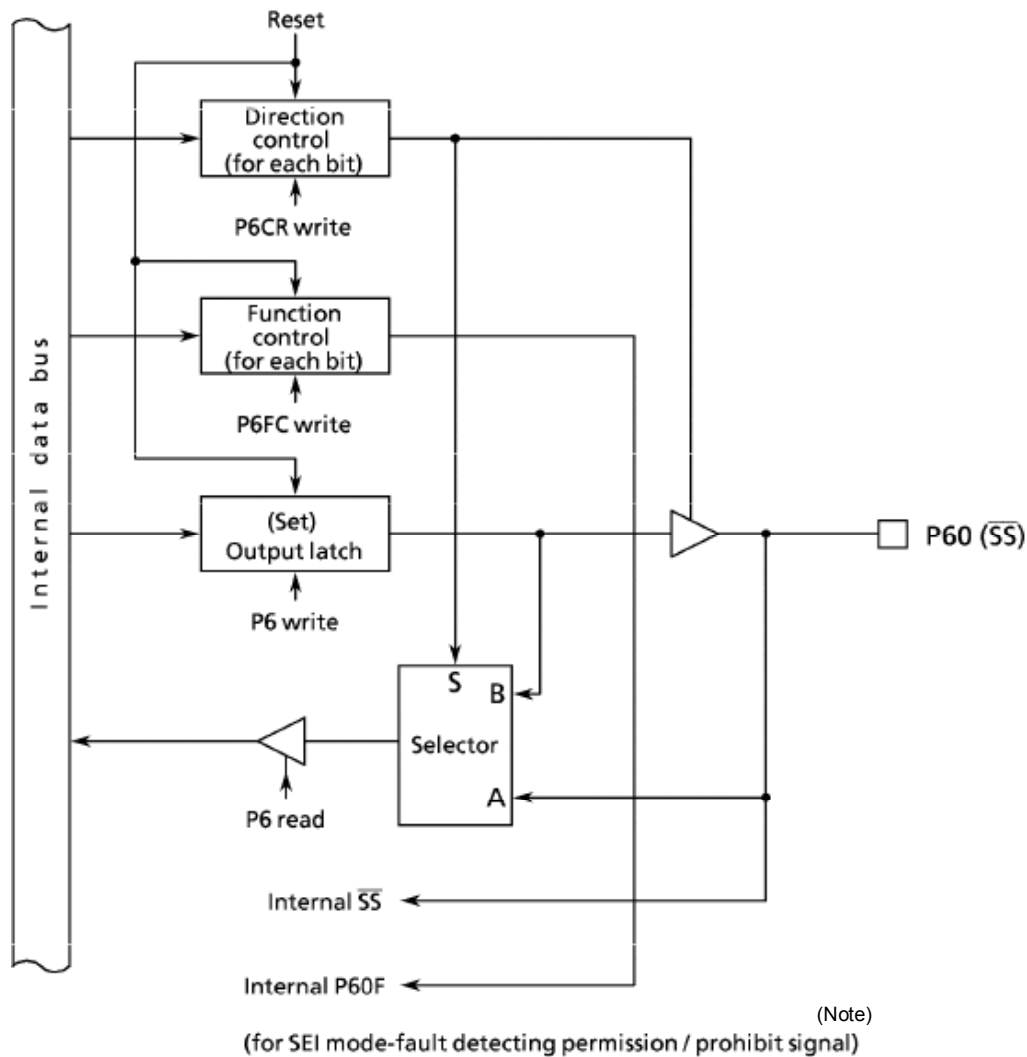

Port 6 is a 4-bit general-purpose input/output port with each bit settable as an input or output.

In addition to functioning as a general-purpose input/output port, port 6 also has a serial expansion interface function (\overline{SS} , MOSI, MISO and SCLK). The port 6 control register P6CR and the port 6 function register P6FC set the functions.

Reset sets the P60 to P63 output latch to 1. Reset also clears all bits of the P6CR and P6FC register to 0, setting port 6 to a general-purpose input port.

(1) Port 60 (\overline{SS})

In addition to being a general-purpose input/output port, port 60 also functions as the \overline{SS} pin.

Note: There is no Mode fault detection.

Figure 3.5.20 Port 6 (P60)

(2) Port 61, 62, 63 (MOSI, MISO, SCLK)

In addition to being general-purpose input/output ports, port 61 also functions as the MOSI pin, port 62 also functions as the MISO pin, and port 63 also functions as the SCLK pin.

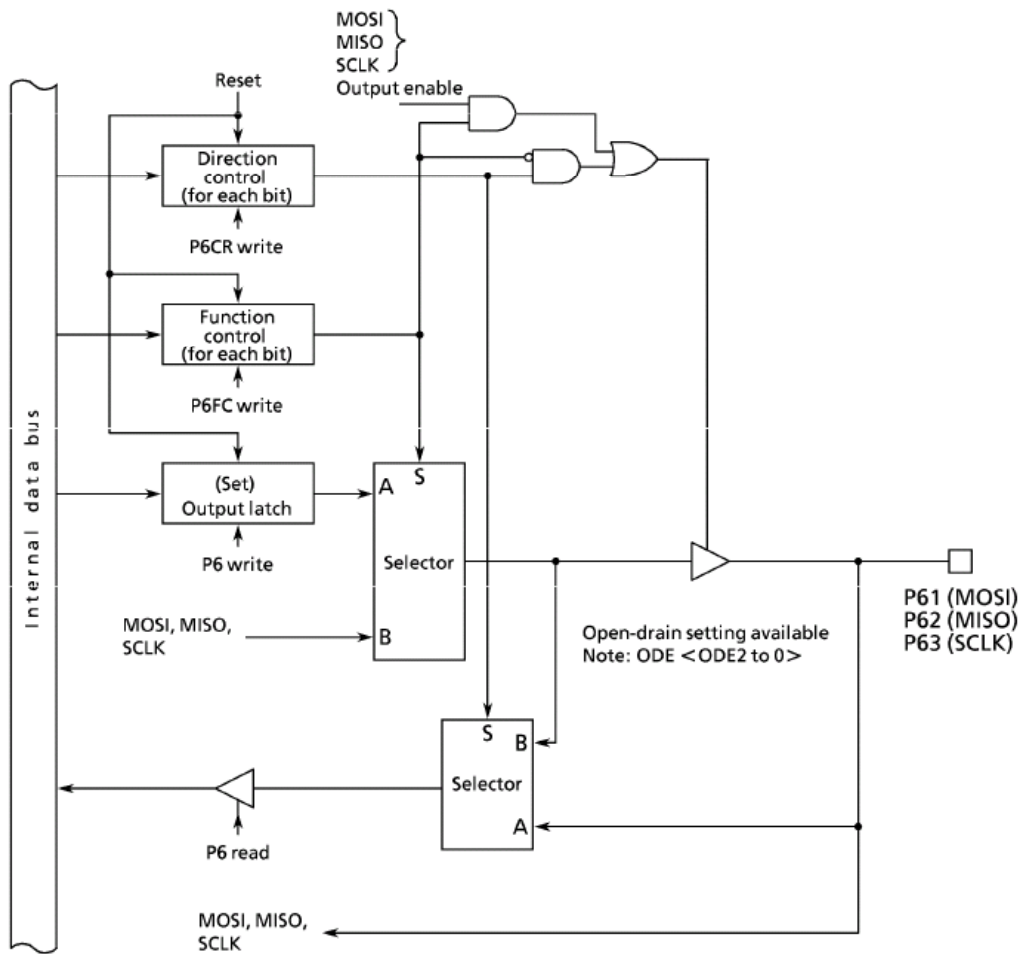

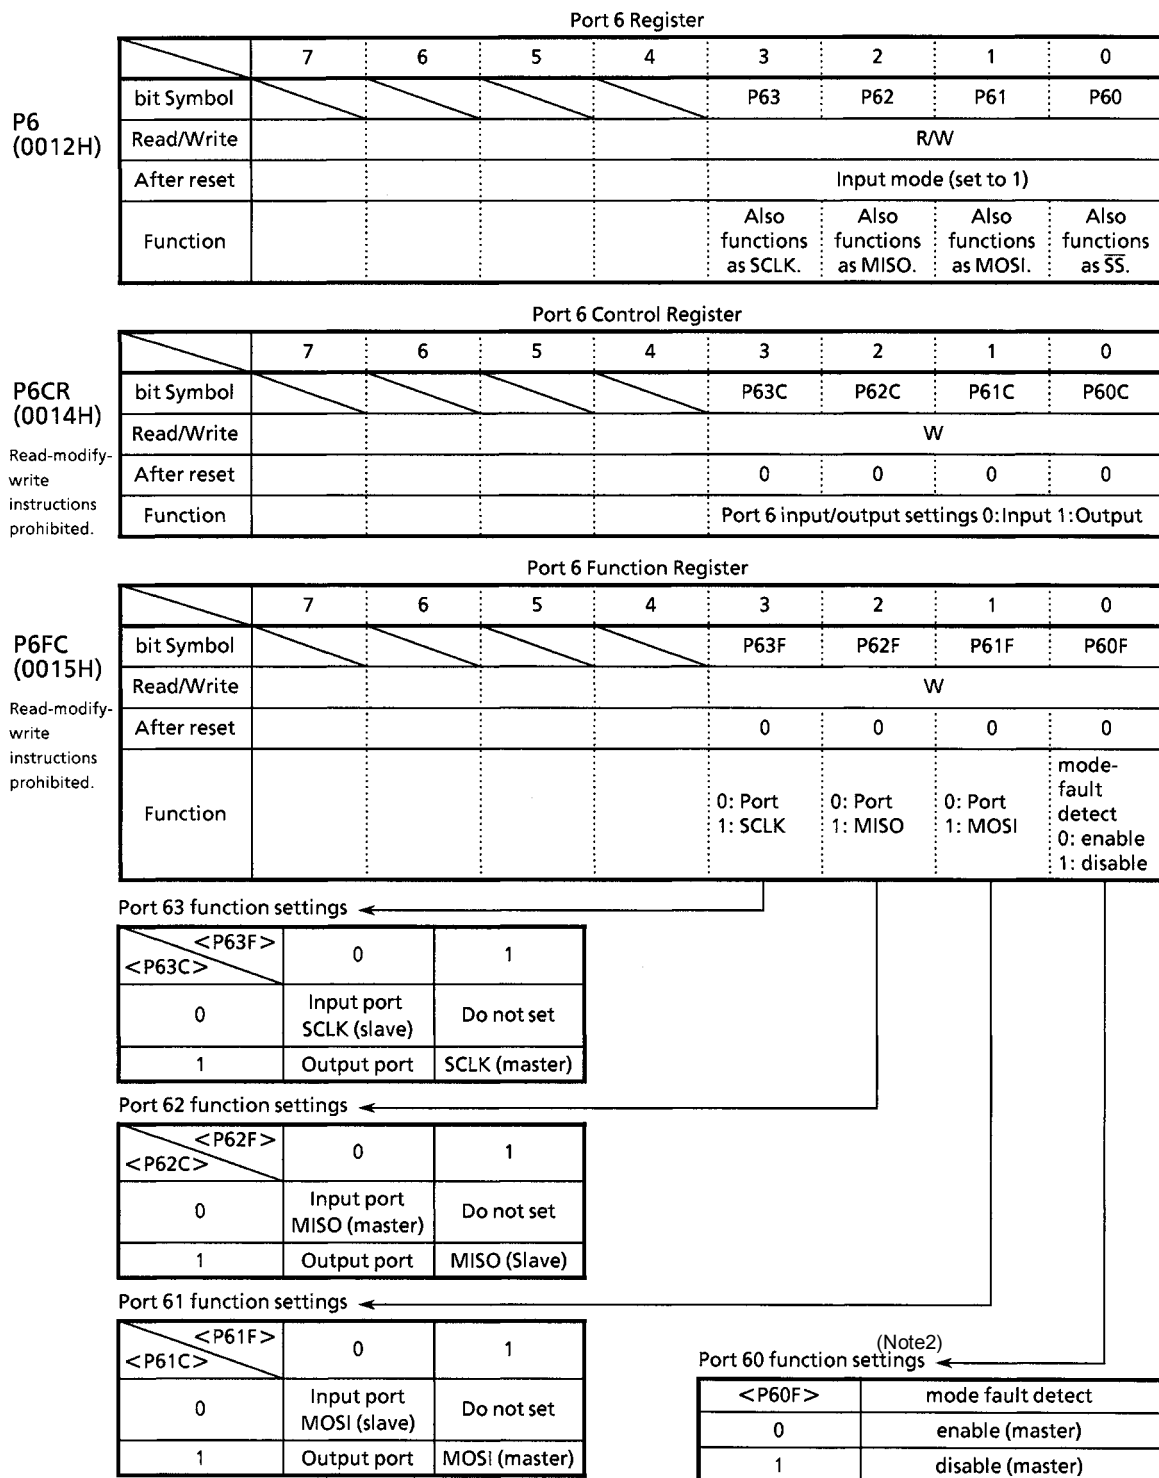

Figure 3.5.21 Port 6 (P61, P62, P63)

Note: When setting pins MOSI, MISO, and SCLK to open drain output, set the open drain enable register ODE $\langle ODE2:0 \rangle$ to 1.
 Pins P60/ \overline{SS} (master/slave), P61/MOSI (slave), P62/MISO (master), and P63/SCLK (slave) do not have port/function switching registers. Therefore even when the pins are used as input ports, data are still input to SEI as function data.

Note2: There is no Mode fault detection. Set $\langle P60F \rangle$, which is the enable/disable bit for Mode fault detection, to "1" to disable the Mode fault detection function.

Figure 3.5.22 Register for Port 6

3.5.8 Port 7 (P70 to P75)

Port 7 is a 6-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to functioning as general-purpose input/output port pins, port 7 pins also function as event count inputs for the 8-bit timer, outputs for the 8-bit timer, and INT1 to 4 inputs for the external interrupt function.

Port 7 control register P7CR and port 7 function register P7FC set the port 7 functions.

Reset clears all bits of the output latch register and P7CR to 0, setting all pins to input mode.

To enable the timer output function, write 1 to the corresponding bits in both P7CR and P7FC.

(1) Port 70, 73 (TI0/INT1, T14/INT3)

In addition to functioning as a general-purpose input/output port, port 70 can also function as the event count input TI0 for timer 0 and as the external interrupt request input INT1.

In addition to functioning as a general-purpose input/output port, port 73 can also function as the event count input TI4 for timer 4 and as the external interrupt request input INT3.

Caution when using INT1 and INT3 interrupts

Input is always enabled for the INT1 and INT3 external interrupt requests.

Caution is required if port 70 or 73 is used as a general-purpose input/output port or a timer event count input while the INT1 and INT3 interrupt functions are in use. This is because rising edges on these input/output signals generate interrupt requests.

Caution when using timer event count inputs TI0 and TI4

Input is always enabled for the timer event count inputs TI0 and TI4.

Caution is required if port 70 or 73 is used as a general-purpose input/output port or an INT1 or INT3 interrupt during event counting based on TI0 or TI4. This is because these input/output signals trigger an event count on the timer.

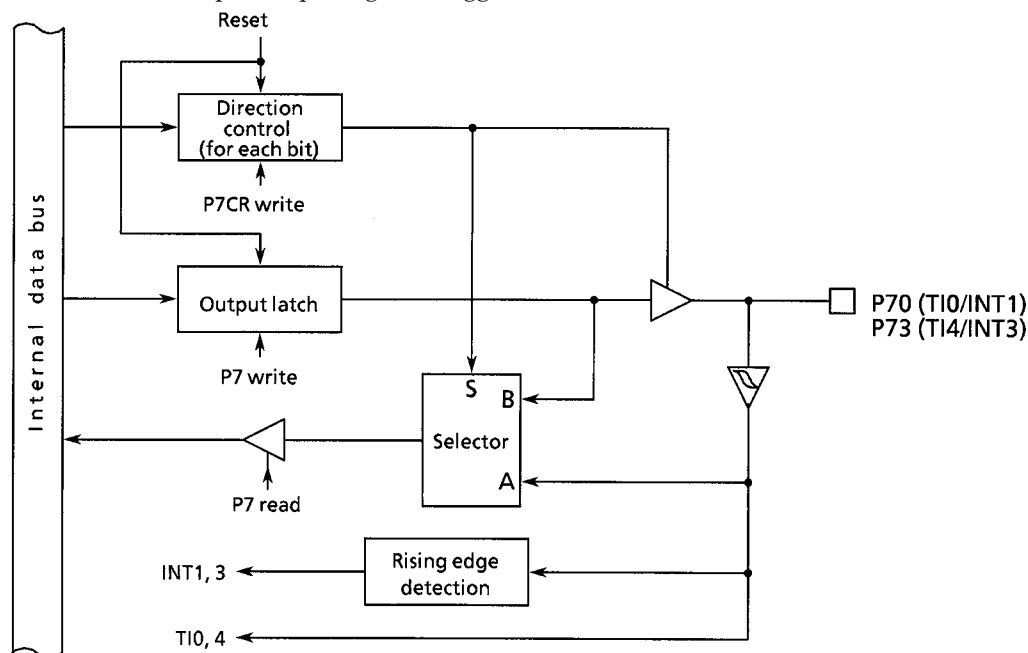

Figure 3.5.23 Port 7 (P70, P73)

(2) Port 71, 74 (TO1, TO5)

In addition to functioning as a general-purpose input/output port, port 71 also functions as TO1 for output of timers 0 and 1. In addition to functioning as a general-purpose input/output port, port 74 also functions as TO5 for output of timers 4 and 5.

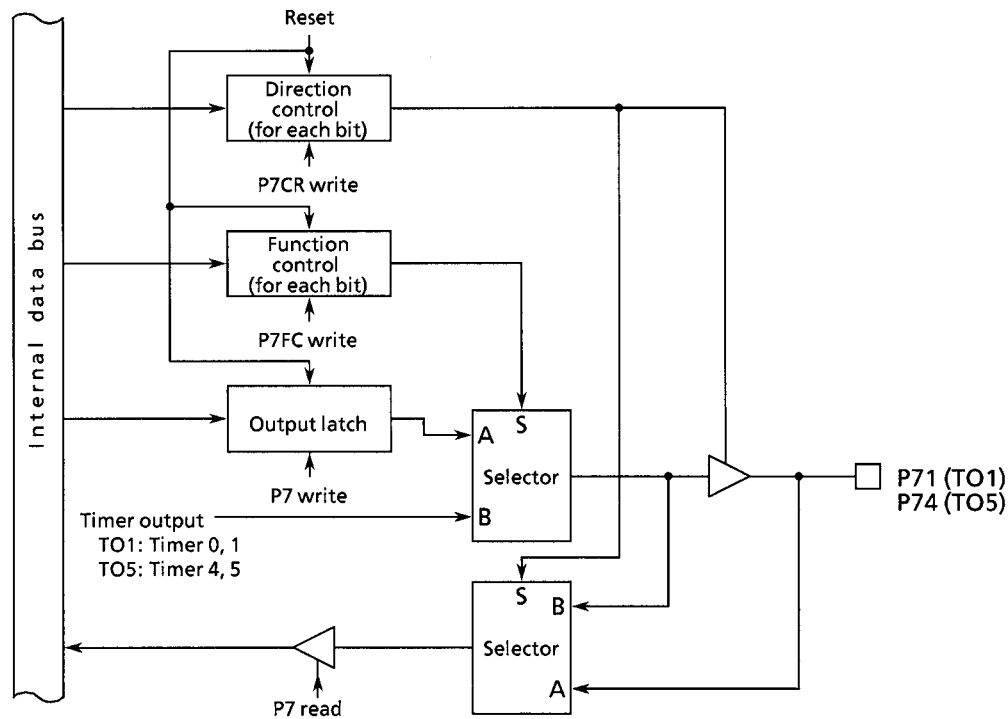

Figure 3.5.24 Port 7 (P71, P74)

(3) Port 72, 75 (TO3/INT2, TO7/INT4)

In addition to functioning as a general-purpose input/output port, port 72 also functions as TO3 for output of timers 2 and 3 and as the external interrupt request input INT2.

In addition to functioning as a general-purpose input/output port, port 75 also functions as TO7 for output of timers 6 and 7 and as the external interrupt request input INT4.

Caution when using INT2 or INT4 interrupts

Input is always enabled for the INT2 and INT4 external interrupt requests.

Caution is required if port 72 or 75 is used as a general-purpose input/output port or timer event count input port while the INT2 and INT4 interrupt functions are in use. This is because rising edges on these input/output signals generate interrupt requests.

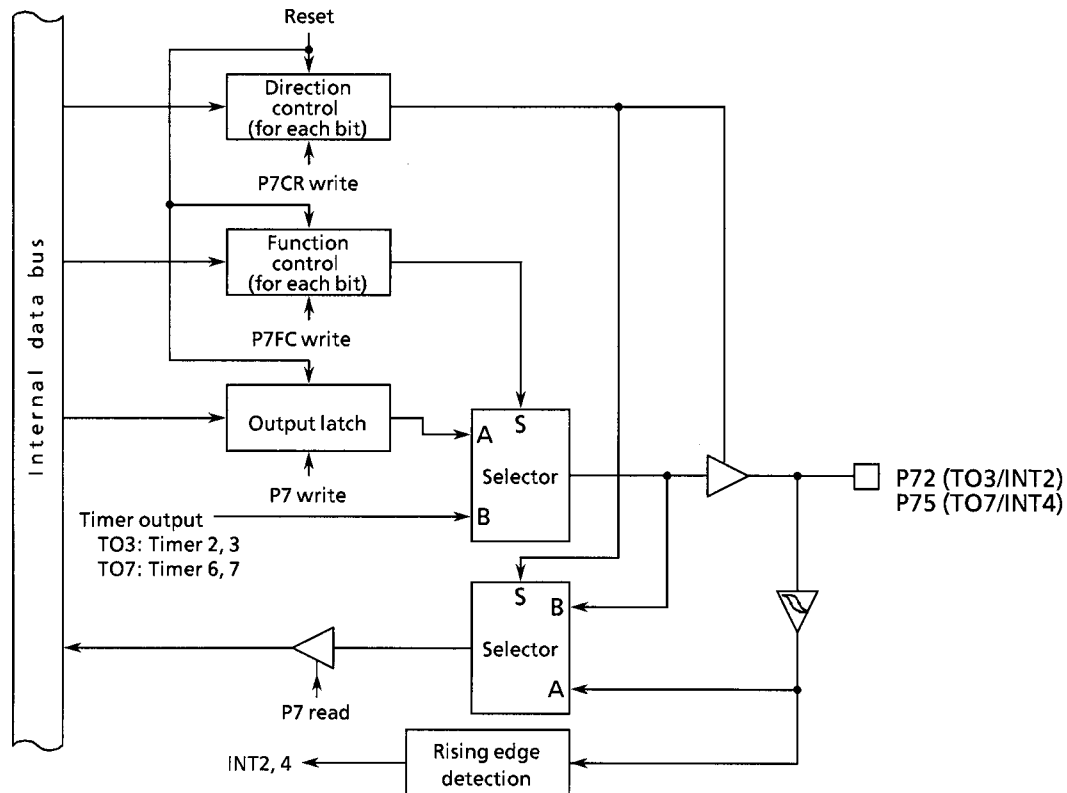

Figure 3.5.25 Port 7 (P72, P75)

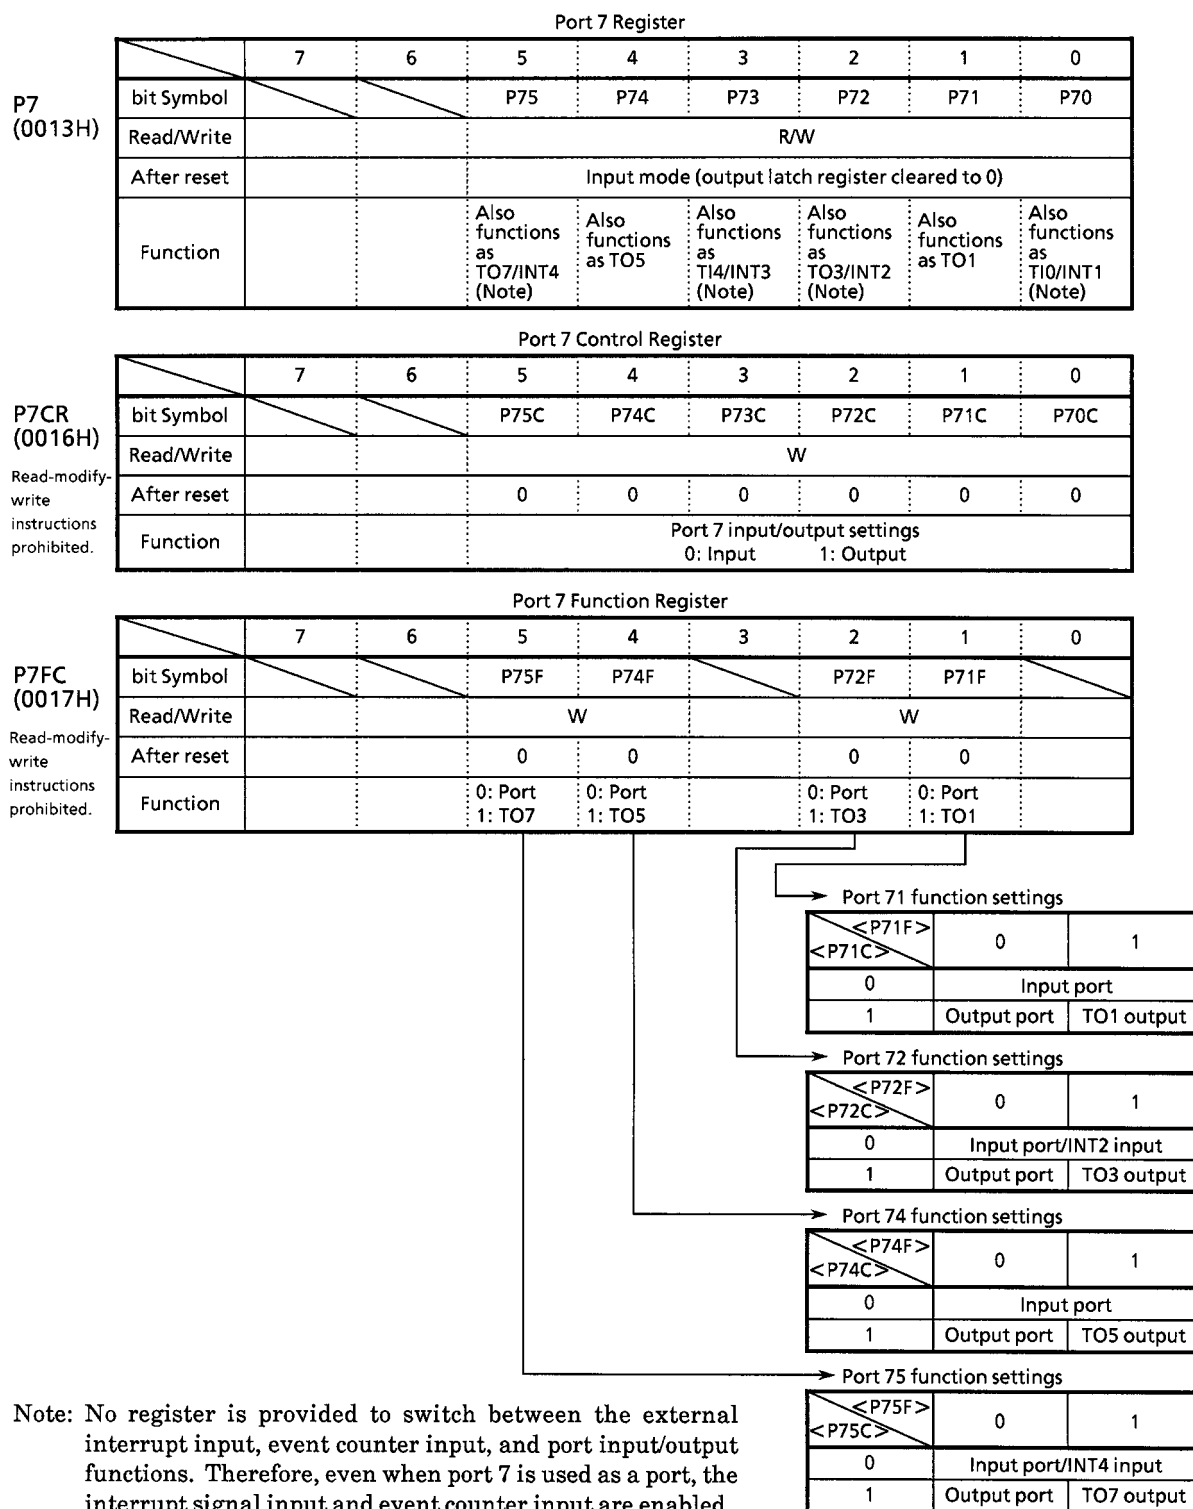

Figure 3.5.26 Register for Port 7

3.5.9 Port 8 (P80 to P87)

Port 8 is an 8-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to being a general-purpose input/output port, port 8 also functions as a serial channel TxD output, RxD input, SCLK input/output, and CAN controller Tx output and Rx input.

Port 8 control register P8CR and port 8 function register P8FC set the functions.

Reset sets all bits of the output latch to 1. It also clears all bits of the P8CR and P8FC registers to 0, setting port 8 to input mode using pull-up resistors.

Port pins 80 and 83 have a programmable open drain function.

(1) Ports 80, 83, 86 (TxD0, TxD1, Tx)

Ports 80, and 83 function as the serial channel TxD0 and TxD1 outputs as well as input/output ports.

These ports have a programmable open drain function. Setting open drain disables pull-up.

Port 86 functions as the CAN controller Tx output as well as input/output ports.

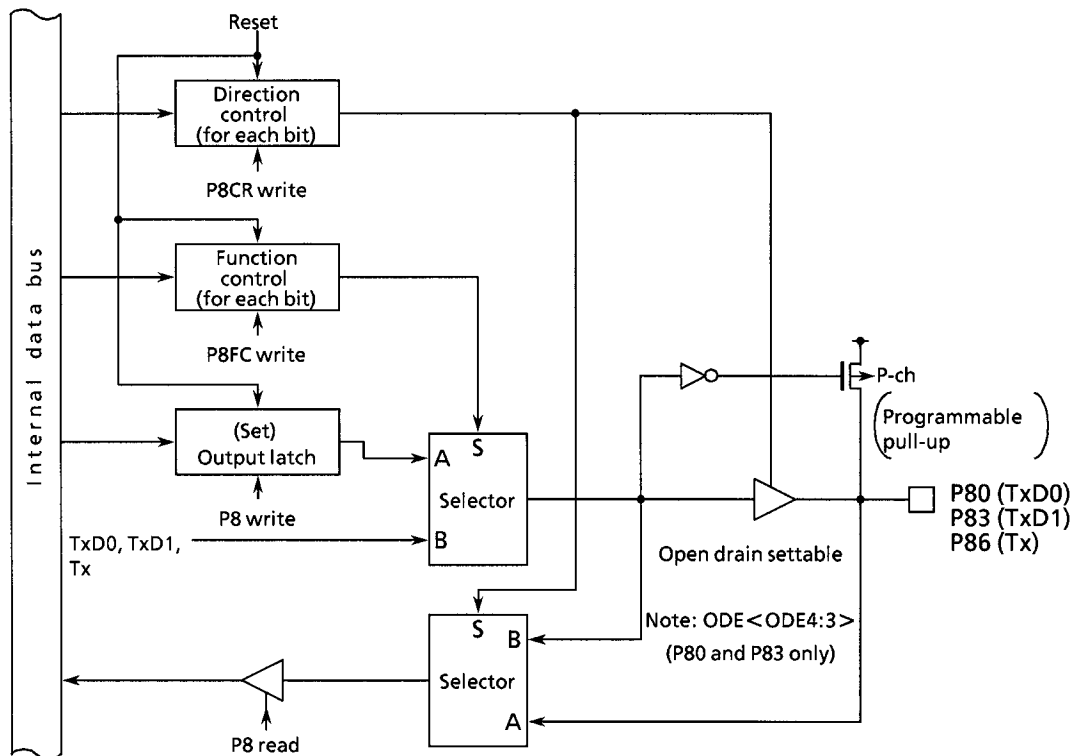

Figure 3.5.27 Port 8 (P80, P83, P86)

(2) Port 81, 84, 87 (RxD0, RxD1, Rx)

Ports 81 and 84 function as serial channel RxD0 and RxD1 inputs as well as input/output ports.

Port 87 functions as the CAN controller Rx input as well as input/output port.

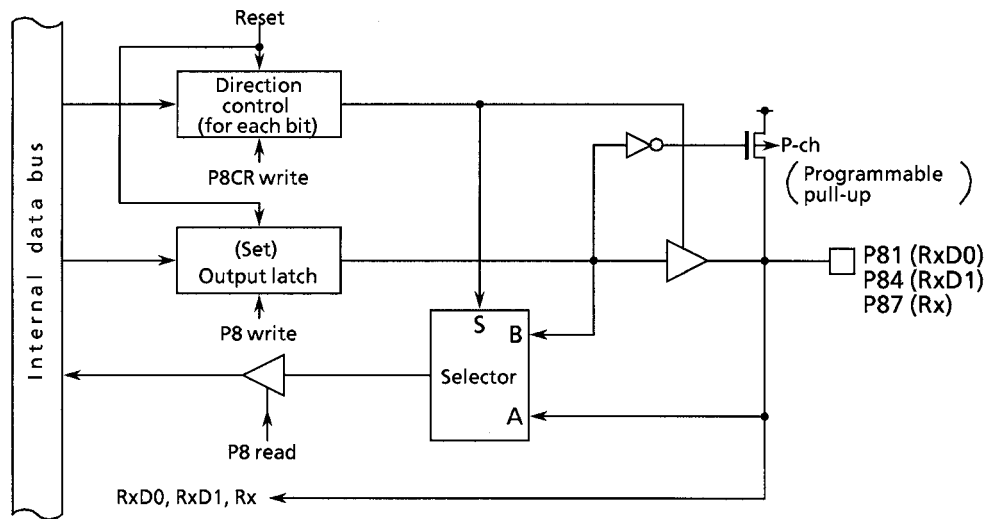

Figure 3.5.28 Port 8 (P81, P84, P87)

(3) Port 82 (SCLK0/ $\overline{\text{CTS0}}$)

Port 82 functions as the SCLK0 input/output for serial channel 0 as well as an input/output port. The port also functions as the $\overline{\text{CTS0}}$ input.

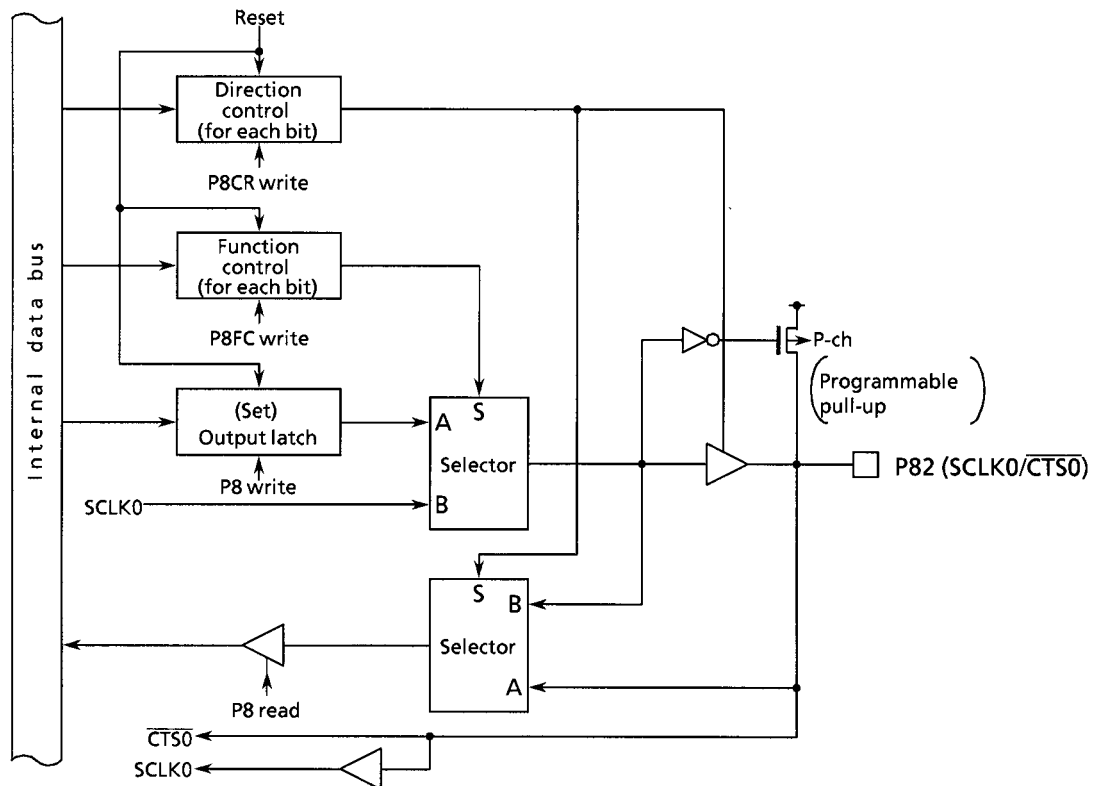

Figure 3.5.29 Port 8 (P82)

(4) Port 85 (SCLK1/ $\overline{\text{CTS1}}$)

Port 85 functions as the SCLK1 input/output for serial channel 1 as well as an input/output port. The port also functions as the $\overline{\text{CTS1}}$ input.

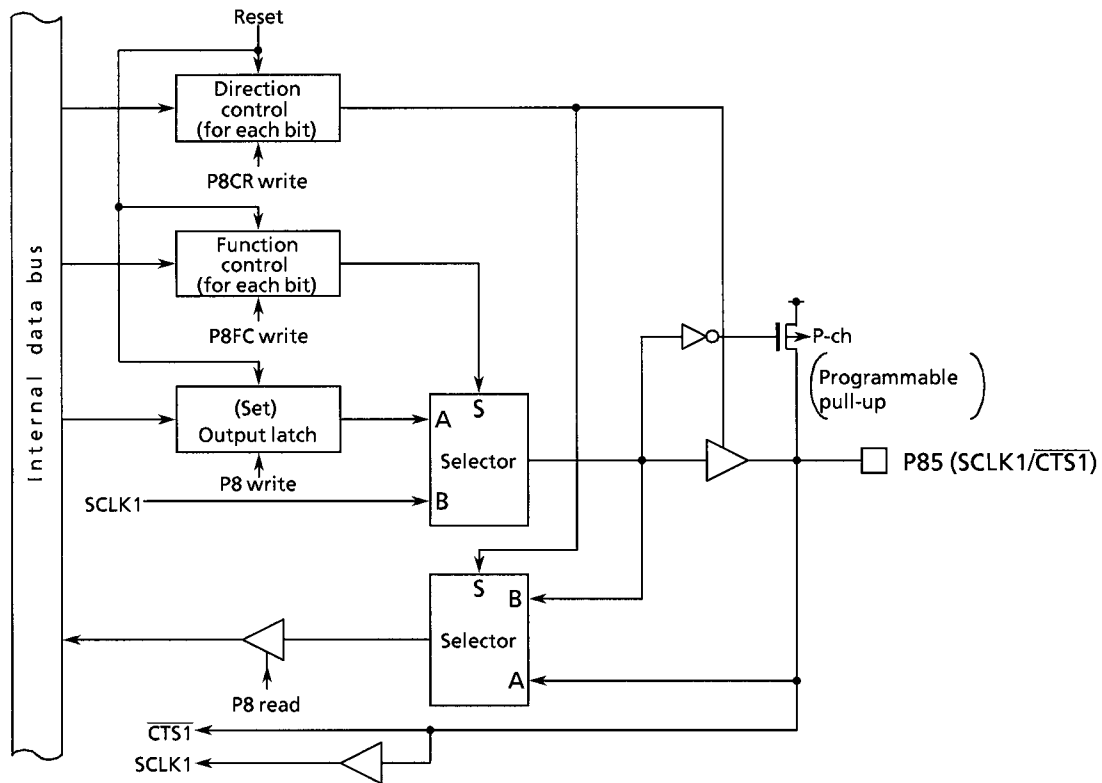

Figure 3.5.30 Port 8 (P85)

Port 8 Register								
	7	6	5	4	3	2	1	0
bit Symbol	P87	P86	P85	P84	P83	P82	P81	P80
Read/Write	R/W							
After reset	Input mode (Set to 1/pulled up)							
Function	Also functions as Rx	Also functions as Tx	Also functions as SCLK1/CTS1	Also functions as Rx/D1	Also functions as Tx/D1	Also functions as SCLK0/CTS0	Also functions as Rx/D0	Also functions as Tx/D0

P8
(0018H)

Note: When port 8 is in input mode, the P8 register controls the internal pull-up resistor. When using port 8 in input mode or in both input and output modes (if a bit is set to input), do not execute read-modify-write instructions. The internal pull-up resistor setting may change depending on the state of the input pin.

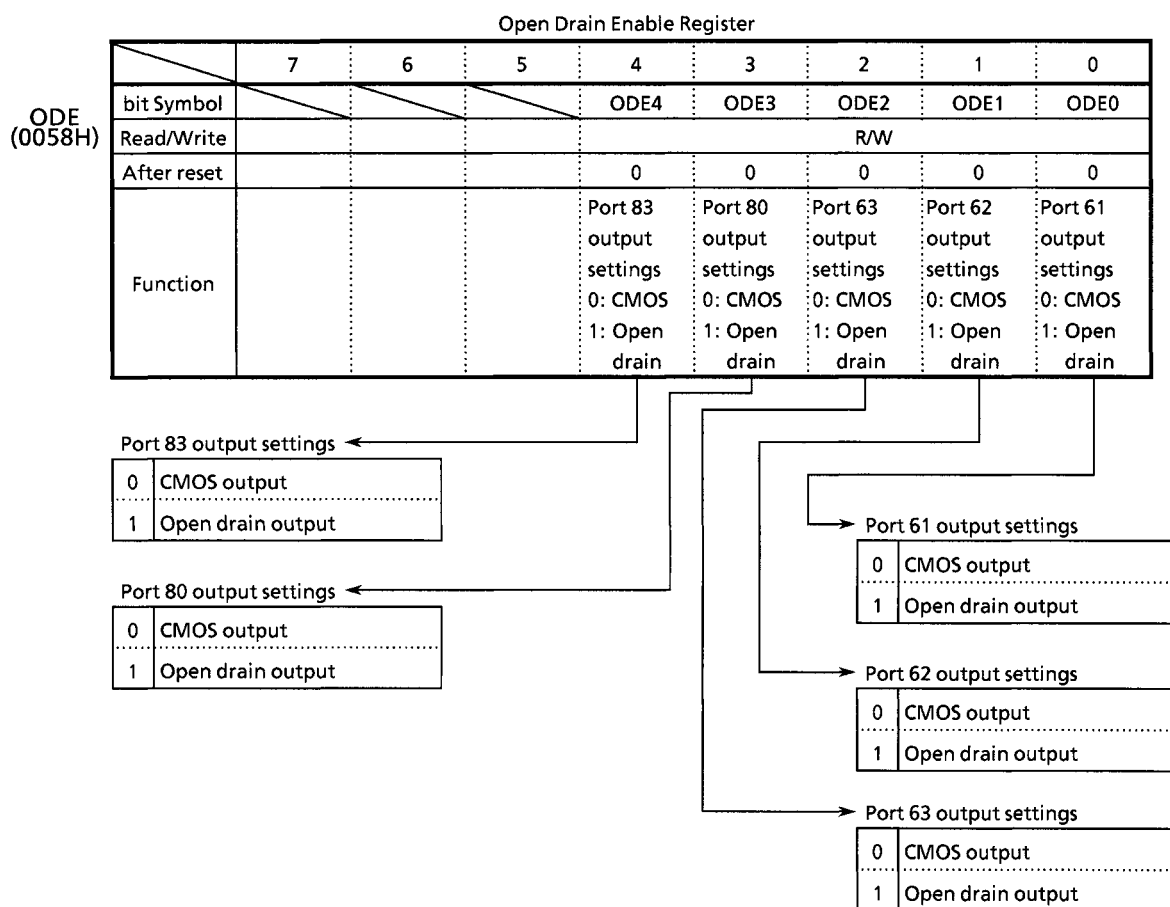

Figure 3.5.31 Register for Port 8 (1/2)

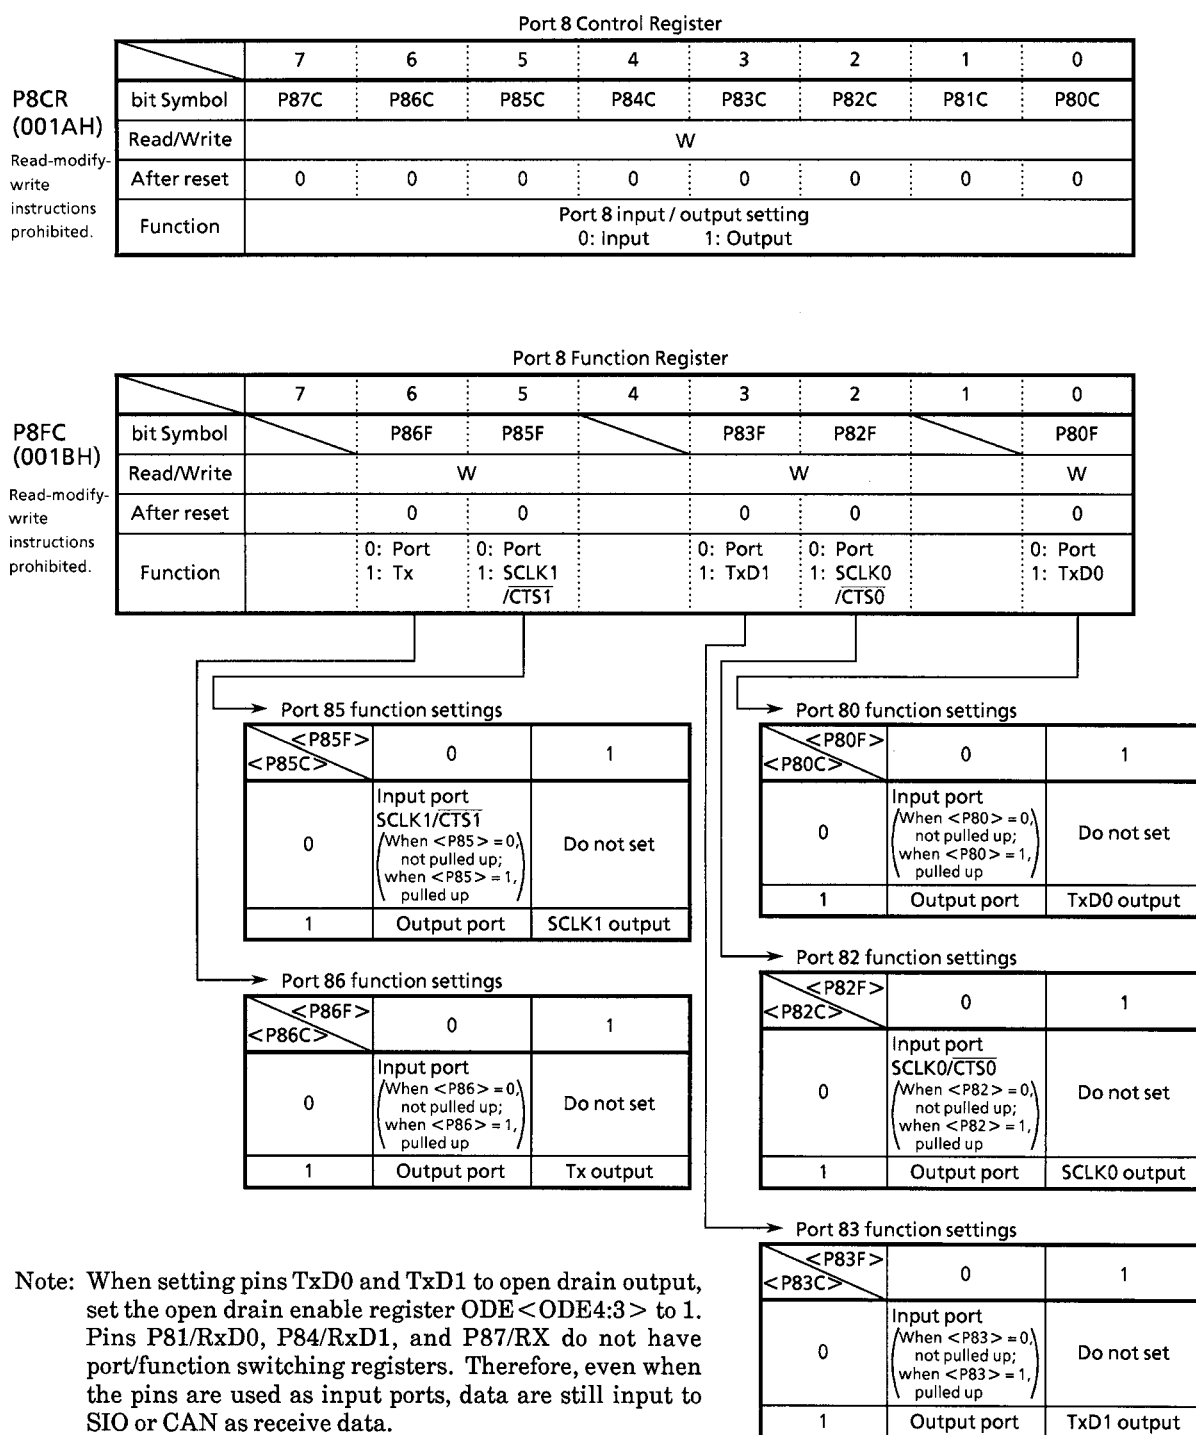

Figure 3.5.31 Register for Port 8 (2/2)

3.5.10 Port 9 (P90 to P96)

Port 9 is a 7-bit general-purpose input/output port with each port bit settable as an input or output.

In addition to its input/output port functions, port 9 also functions as a 16-bit timer input clock pin, a 16-bit timer output pin, and inputs for INT5 to 8. Port 9 control register P9CR and port 9 function register P9FC set the port 9 functions.

A reset clears all bits of the P9 output latch and all bits of the P9CR and P9FC registers to 0, setting port 9 to input mode.

To enable the timer output function, write 1 to the corresponding bit in P9FC.

(1) Ports 90, 91, 94, 95 (TI8/INT5, TI9/INT6, TIA/INT7, TIB/INT8)

In addition to functioning as general-purpose input/output ports, ports 90 and 91 can also function as timer 8 event count inputs TI8 and TI9, and as external interrupt request inputs INT5 and INT6. Ports 94 and 95, in addition to being general-purpose input/output ports, can also function as the timer 9 event count inputs TIA and TIB, and as the external interrupt request inputs INT7 and INT8.

Caution when using INT5 to INT8 interrupts

Input is always enabled for the INT5 to INT8 external interrupt requests.

Caution is required if ports 90, 91, 94, or 95 are used as general-purpose input/output ports or timer event count inputs while the INT5 to INT8 interrupt functions are in use. This is because rising or falling edges on these input/output signals generate interrupt requests.

Caution when using timer event count inputs TI8 to TIB

Input is always enabled for timer event count inputs TI8 to TIB.

Caution is required if ports 90, 91, 94, or 95 are used as general-purpose input/output ports or INT5 to INT8 interrupts during event counting based on TI8 to TIB. This is because these input/output signals trigger an event count on the timer.

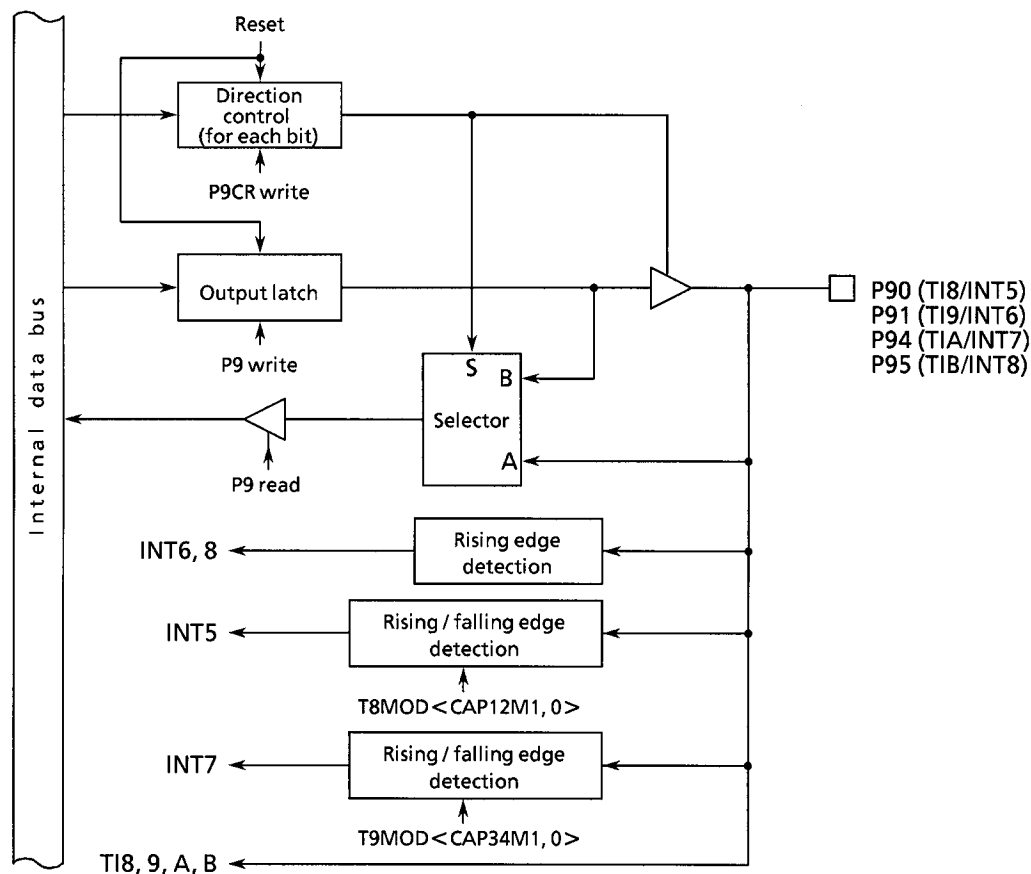

Figure 3.5.32 Port 9 (P90, P91, P94, P95)

(2) Ports 92, 93 (TO8, TO9)

In addition to operating as a general-purpose input/output port, port 92 also functions as the TO8 output for timer 8. Port 93 operates as the TO9 output for timer 8 as well as functioning as a general-purpose input/output port.

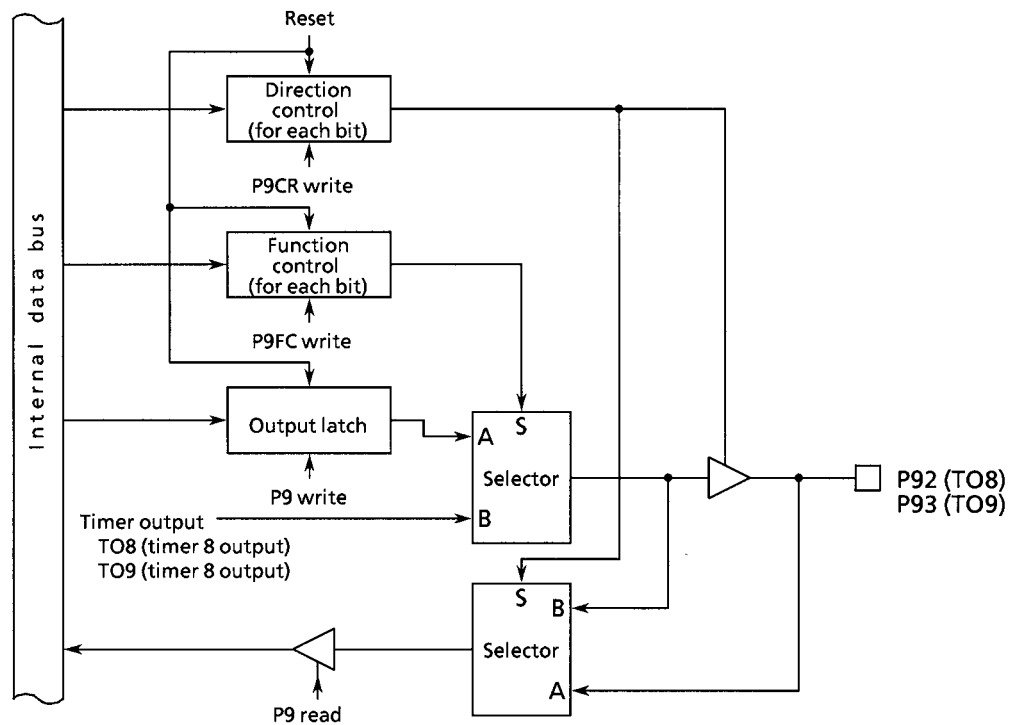

Figure 3.5.33 Port 9 (P92, P93)

(3) Port 96 (TOA/TOB)

In addition to functioning as a general-purpose input/output port, port 96 also functions as the TOA and TOB outputs for timer 9.

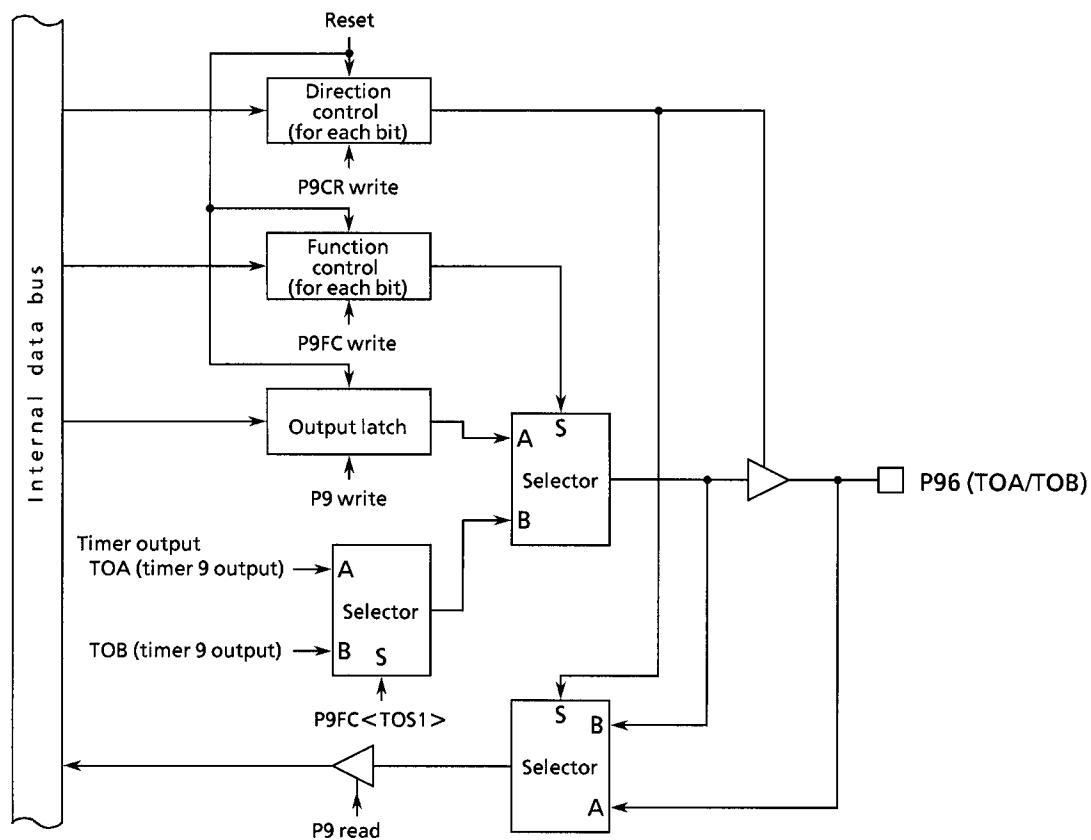

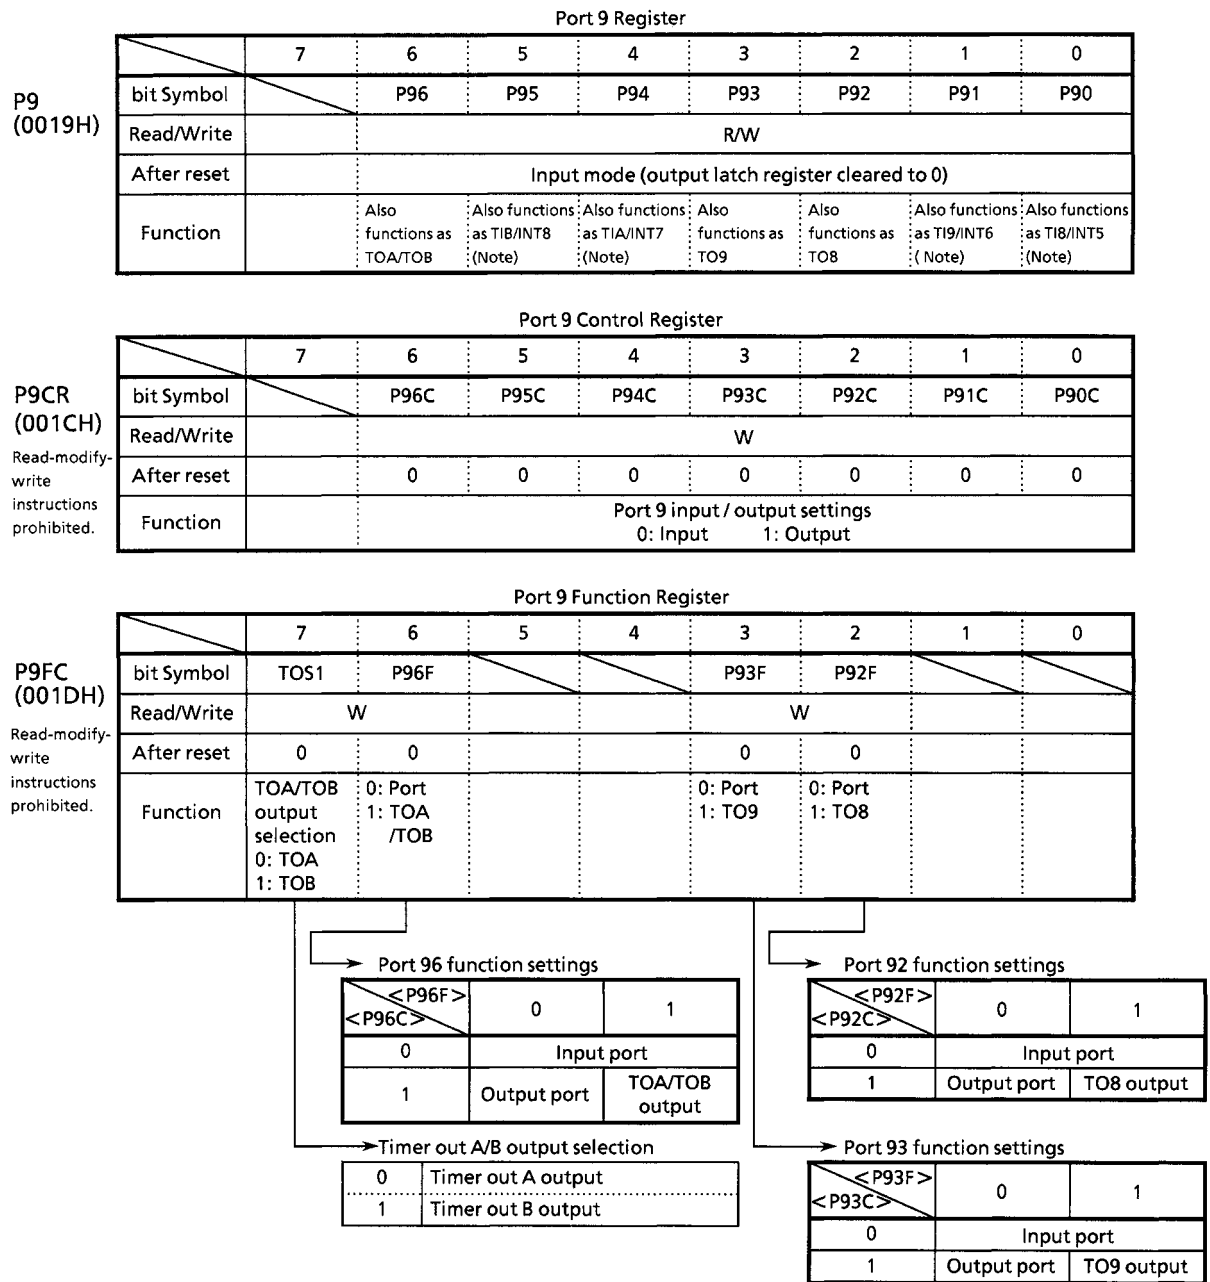

Figure 3.5.34 Port 9 (P96)

Note: No register is provided to switch between the external interrupt input, event counter input, and port input/output functions. Therefore, even when port 9 is used as a port, the interrupt signal input and event counter input are enabled. When using port 9 exclusively as a port, disable the external interrupts (INT5 to 8) and event count inputs (TI8 to B).

Figure 3.5.35 Register for Port 9

3.5.11 Port A (PA0 to PA7)

Port A is an 8-bit input-only port with analog input pins (AN0 to AN7). The PA3 pin also functions as the external trigger input for analog conversion ($\overline{\text{ADTRG}}$).

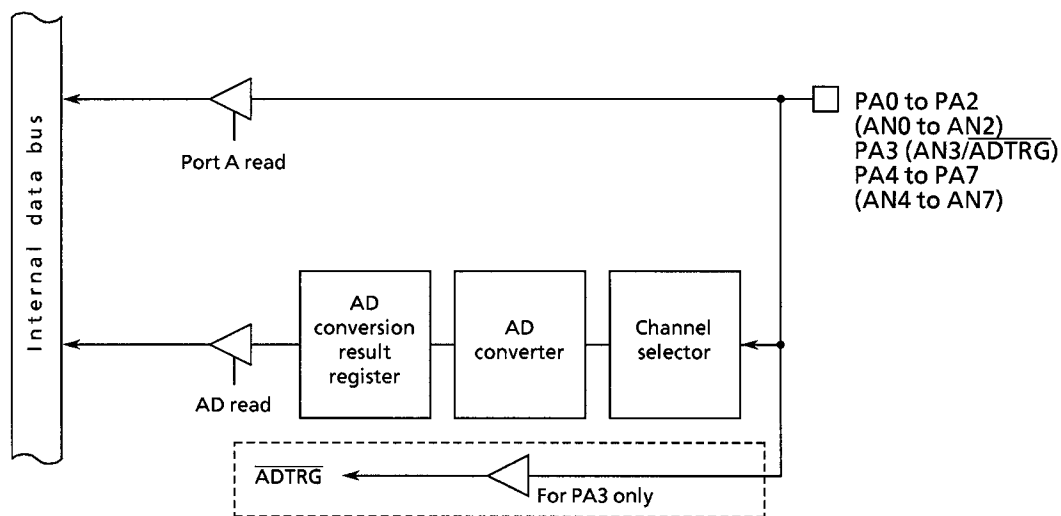

Figure 3.5.36 Port A (PA0 to PA7)

Port A Register								
	7	6	5	4	3	2	1	0
bit Symbol	PA7	PA6	PA5	PA4	PA3	PA2	PA1	PA0
Read/Write	R							
After reset	Input only							
Function	Also functions as AN7	Also functions as AN6	Also functions as AN5	Also functions as AN4	Also functions as AN3 /ADTRG	Also functions as AN2	Also functions as AN1	Also functions as AN0

Note: AD mode register 1, ADMOD1, selects the AD converter input channel.

Figure 3.5.37 Register for Port A

3.6 Bus Width/Wait Controller

In the TMP95CU54A, four user-specifiable address area blocks can be set. The data bus width and number of waits can be set independently for each address area and for others.

Address areas 0 to 3 are set by a combination of memory start address registers MSAR0 to MSAR3 and memory address mask registers MAMR0 to MAMR3.

Use bus width/wait control registers WAITC0 to WAITC3 and WAITCEX to specify the master enable, data bus width, and number of waits for each address area.

The input pins controlling these states are the bus wait request pin ($\overline{\text{WAIT}}$), the external data bus selection pin ($\text{AM8}/\overline{16}$), and the external memory access pin ($\overline{\text{EA}}$). (See 3.1.2, External Data Bus Width Selection Function.)

3.6.1 Specifying address areas

Address areas 0 to 3 are specified using the start address registers MSAR0 to MSAR3 and memory address mask registers MAMR0 to MAMR3.

At each bus cycle, a compare operation is performed to determine if the address on the bus specifies a location in address areas 0 to 3. If the result of the comparison is a match, this indicates an access to the corresponding address area. In this case, the bus cycle operates in accordance with the settings in bus width/wait control register WAITC0 to WAITC3. If the result of the comparison is not a match, this indicates an access to another address area. In this case, the bus cycle operates in accordance with the settings in bus width/wait control register WAITCEX. (See 3.6.2, Bus Width/Wait Control Register.)

(1) Memory Start Address Registers

Figure 3.6.1 shows the memory start address registers. Memory start address registers MSAR0 to MSAR3 set the start address for address areas 0 to 3. Set the upper eight bits (A23 to A16) of the start address in <S23:16>. The lower 16 bits of the start address (A15 to A0) are permanently set to 0. Accordingly, the start address can only be set in 64 Kbyte increments, starting from 000000H. Figure 3.6.2 shows the relationship between the start address and the start address register value.

		Memory Start Address Register (Address areas 0 to 3)							
		7	6	5	4	3	2	1	0
MSAR0 (0094H) / MSAR1 (0096H) / MSAR2 (0098H) / MSAR3 (009AH)	bit Symbol	S23	S22	S21	S20	S19	S18	S17	S16
	Read/Write	R/W							
	After reset	1	1	1	1	1	1	1	1
	Function	Sets start address A23 to A16							

Sets start address of address areas 0 to 3

		to	to
		FF0000H	FFH
FFFFFFH			

Figure 3.6.2 Relationship Between Start Address and Start Address Register Value

(2) Memory address mask registers

Figure 3.6.3 shows the memory address mask registers. Memory address mask registers MAMR0 to MAMR3 are used to set the size of address areas 0 to 3 by specifying a mask for each bit of the start address set in memory start address registers MSAR0 to MSAR3. The compare operation used to determine if an address is in the address areas 0 to 3 is only performed for bus address bits corresponding to bits set to 0 in these registers.

Also, the address bits that can be masked by MAMR0 to MAMR3 differ between address areas 0 to 3. Accordingly, the size that can be set for each area is different.

Memory address mask register (address area 0)								
	7	6	5	4	3	2	1	0
bit Symbol	V20	V19	V18	V17	V16	V15	V14 to 9	V8
MAMR0 (0095H) Read/Write	R/W							
After reset	1	1	1	1	1	1	1	1
Function	Sets size of address area 0 0: Used for address compare							

Address area 0 can be set within the following range: 256 bytes to 2 Mbytes.

Memory address mask register (address area 1)								
	7	6	5	4	3	2	1	0
bit Symbol	V21	V20	V19	V18	V17	V16	V15 to 9	V8
MAMR1 (0097H) Read/Write	R/W							
After reset	1	1	1	1	1	1	1	1
Function	Sets size of address area 1 0: Used for address compare							

Address area 1 can be set within the following range: 256 bytes to 4 Mbytes.

Memory address mask register (address areas 2 and 3)								
	7	6	5	4	3	2	1	0
bit Symbol	V22	V21	V20	V19	V18	V17	V16	V15
MAMR2 / MAMR3 (0099H) / (009BH) Read/Write	R/W							
After reset	1	1	1	1	1	1	1	1
Function	Sets size of address areas 2 and 3 0: Used for address compare							

Address areas 2 and 3 can be set within the following range: 32 Kbyte to 8 Mbytes.

Figure 3.6.3 Memory Address Mask Registers

(3) How to set memory start addresses and address areas

Figure 3.6.4 shows an example of specifying a 64 Kbyte address area starting from 010000H using address area 0.

Set 01H in memory start address register MSAR0<S23:16> (corresponding to the upper 8 bits of the start address). Next, calculate the difference between the start address and the anticipated end address (01FFFFH) based on the size of address area 0. Bits 20 to 8 of the result correspond to the mask value to be set for address area 0. Setting this value in memory address mask register MAMR0<V20:8> sets the area size. This example sets 07H in MAMR0 to specify a 64 Kbyte area.

Figure 3.6.4 Address Area 0 Setting Example

After a reset, MSAR0 to MSAR3 and MAMR0 to MAMR3 are set to FFH. WAITC0<B0E>, WAITC1<B1E>, and WAITC3<B3E> are reset to 0. This disables address areas 0, 1 and 3. However, as WAITC2 <B2M> is reset to 0 and WAITC2<B2E> to 1, address area 2 is enabled from 000CA0H to 0021FFFH and from 002340H to FE7FFFH. Also, the bus width and number of waits specified in WAITCEX are used for accessing addresses outside the specified address areas 0 to 3. (See 3.6.2 Bus Width/Wait Control Register.)

(4) Address area size specifications

Table 3.6.1 shows the relationship between address area and area size. Δ indicates areas that cannot be set by memory start address register and memory address mask register combinations. When setting an area size using a combination indicated by Δ , set the start address in the desired steps starting from 000000H.

If the address area 2 is set to 16M-byte or if two or more areas overlap, the smaller address area number has the higher priority.

Example: When setting address area 0 as a 128 Kbyte area:

[1] Available start addresses

000000H	}	128 Kbytes	Any of these start addresses can be set.
020000H			
040000H	}	128 Kbytes	
060000H			
:			

[2] Unavailable start addresses

000000H	}	64 Kbytes	← This exceeds the size of the steps that can be set. In this case, the following start addresses cannot set the desired area size.
010000H			
030000H	}	128 Kbytes	
050000H			
:			

Table 3.6.1 Address Area and Area Size

Size (bytes) Address area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
0	O	O	O	O	Δ	Δ	Δ	Δ	Δ		
1	O	O		O	Δ	Δ	Δ	Δ	Δ	Δ	
2			O	O	Δ	Δ	Δ	Δ	Δ	Δ	Δ
3			O	O	Δ	Δ	Δ	Δ	Δ	Δ	Δ

3.6.2 Bus Width/Wait Control Registers

Figure 3.6.5 lists the bus width/wait control registers. The master enable/disable, data bus width, and number of wait states for each address area 0 to 3 and others are set in their respective bus width/wait control registers, WAITC0 to WAITC3 and WAITCEX.

Bus Width/Wait Control Register								
	7	6	5	4	3	2	1	0
WAITC0 (0090H)	bit Symbol	B0E			B0BUS	B0W2	B0W1	B0W0

Figure 3.6.5 Bus Width/Wait Control Registers

(1) Master enable bits

Bit 7 (<B0E>, <B1E>, <B2E>, and <B3E>) of the bus width/wait control registers is the master bit used to enable or disable settings for the address area. Writing 1 to the bit enables the settings. Reset disables (sets to 0) <B0E>, <B1E>, and <B3E>, and enables (sets to 1) <B2E>.

(2) Selection of data bus width

Bit 3 (<B0BUS>, <B1BUS>, <B2BUS>, <B3BUS>, and <BEXBUS>) of the bus width/wait control registers specifies the width of the data bus. Set 0 to access memory when using a 16-bit data bus. Set 1 when using an 8-bit data bus.

Connect the $\overline{\text{EA}}$ and AM8/16 pins to VCC. This enables external memory to be accessed using the data bus width set in the data bus width select bit.

This method of changing the data bus width depending on the address being accessed is called dynamic bus sizing. For details of this bus operation, see Table 3.6.2.

Table 3.6.2 Dynamic Bus Sizing

Operand Data Bus Width	Operand Start Address	Memory Data Bus Width	CPU Address	CPU Data	
				D15 to D8	D7 to D0
8-bit	2n + 0 (Even number)	8 bits	2n + 0	xxxxx	b7 to b0
		16 bits	2n + 0	xxxxx	b7 to b0
	2n + 1 (Odd number)	8 bits	2n + 1	xxxxx	b7 to b0
		16 bits	2n + 1	b7 to b0	xxxxx
16-bit	2n + 0 (Even number)	8 bits	2n + 0	xxxxx	b7 to b0
			2n + 1	xxxxx	b15 to b8
	2n + 1 (Odd number)	16 bits	2n + 0	b15 to b8	b7 to b0
		8 bits	2n + 1	xxxxx	b7 to b0
			2n + 2	xxxxx	b15 to b8
		16 bits	2n + 1	b7 to b0	xxxxx
32-bit	2n + 0 (Even number)	8 bits	2n + 0	xxxxx	b7 to b0
			2n + 1	xxxxx	b15 to b8
			2n + 2	xxxxx	b23 to b16
			2n + 3	xxxxx	b31 to b24
	2n + 1 (Odd number)	16 bits	2n + 0	b15 to b8	b7 to b0
			2n + 2	b31 to b24	b23 to b16
		8 bits	2n + 1	xxxxx	b7 to b0
			2n + 2	xxxxx	b15 to b8
			2n + 3	xxxxx	b23 to b16
			2n + 4	xxxxx	b31 to b24
		16 bits	2n + 1	b7 to b0	xxxxx
			2n + 2	b23 to b16	b15 to b8
			2n + 3	xxxxx	b31 to b24
			2n + 4	xxxxx	b31 to b24

xxxxx: Indicates that the input data from these bits are ignored during a read. During a write, indicates that the bus for these bits goes to high impedance; also, that the write strobe signal for the bus remains inactive.

(3) Wait control

Bits 2 to 0 (<B0W2:0>, <B1W2:0>, <B2W2:0>, <B3W2:0>, and <BEXW2:0>) of the bus width/wait control registers specify the number of waits to insert.

The following types of wait operation can be specified using combinations of these bits. Do not set combinations other than those listed in the table.

Table 3.6.3 Wait Operation Settings

<BxW2:0>	No. of Waits	Wait Operation
000	2WAIT	Inserts a wait of two states, irrespective of the $\overline{\text{WAIT}}$ pin state.
001	1WAIT	Inserts a wait of one state, irrespective of the $\overline{\text{WAIT}}$ pin state.
010	1WAIT + N	Samples the state of the $\overline{\text{WAIT}}$ pin after inserting a wait of one state. If the $\overline{\text{WAIT}}$ pin is low, the waits continue and the bus cycle is extended until the pin goes high.
011	0WAIT	Ends the bus cycle without a wait, regardless of the $\overline{\text{WAIT}}$ pin state.
100	0 + NWAIT	Continuously samples the $\overline{\text{WAIT}}$ pin state and inserts waits if the pin is low, extending the bus cycle until the pin goes high.

Figures 3.6.6 and 3.6.7 show the timing for $N = 0, 1$ when the setting is $0 + \text{NWAIT}$.

For the timings for settings other than $0 + \text{NWAIT}$, see Figures 7.1 to 7.5 in 7. Basic Timing, Chapter 3, TLCS-900/H CPU.

Reset sets these bits to 000 (2 WAIT).

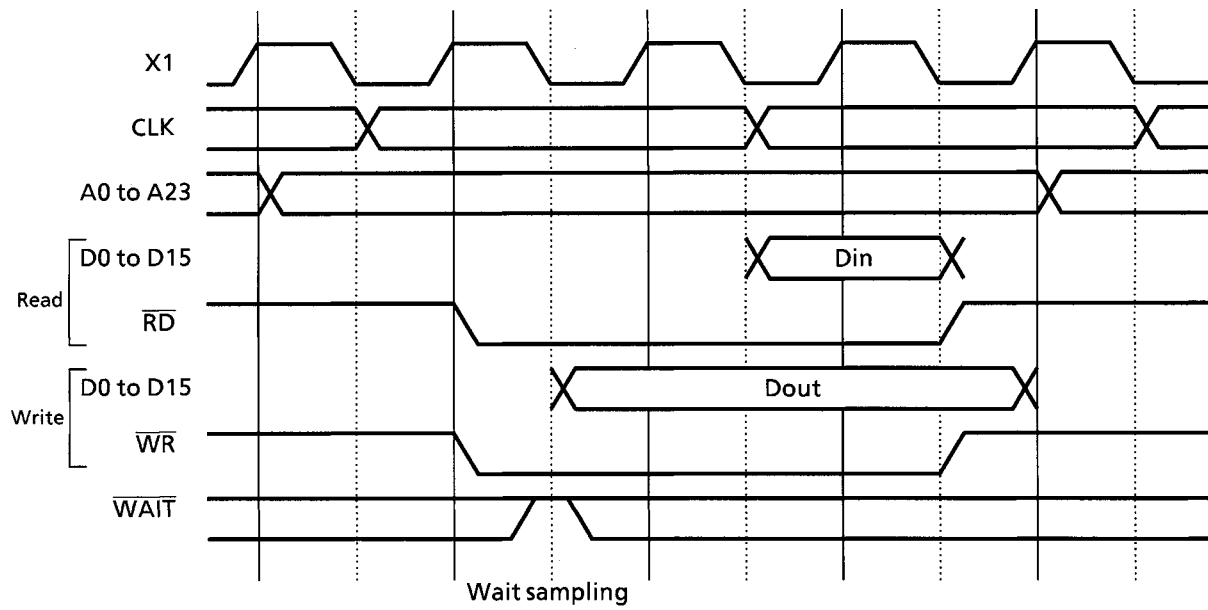

Figure 3.6.6 0 + N WAIT Read/Write Cycle (When N = 0)

Figure 3.6.7 0 + N WAIT Read/Write Cycle (When N = 1)

(4) Bus width and wait control outside address areas 0 to 3

The bus width/wait control register WAITCEX controls the bus width and number of waits when locations outside the four user-specified address area blocks 0 to 3 are accessed. The WAITCEX register settings are always enabled for areas other than address areas 0 to 3.

(5) 16M-byte area/address setting area selection

Setting the bus width/wait control register WAITC2<B2M> to 0 selects a 16M-byte address area (000CA0H to 0021FFH, and 002340H to FE7FFFH) for address area 2. Setting WAITC2<B2M> to 1 selects the address area specified by start address register MSAR2 and address mask register MAMR2 for address area 2, and likewise for address area 0, 1, and 3. Reset clears this bit to 0 and selects a 16M-byte address area.

(6) Bus width/wait control setting procedure

When using the bus width/wait control function, set the registers as follows:

[1] Set memory start address registers MSAR0 to MSAR3.

Set the start addresses of address areas 0 to 3.

[2] Set memory address mask registers MAMR0 to MAMR3.

Set the size of address areas 0 to 3.

[3] Set control registers WAITC0 to WAITC3.

Set the data bus width, number of waits, and master enable/disable for address areas 0 to 3.

In the case of addresses, if one of the address areas 0 to 3 is set, but an internal I/O, RAM or ROM area is specified, the CPU accesses the internal area.

Setting example:

This example sets the address area 0 as 010000H to 01FFFFH (64 Kbyte area) with a 16-bit bus and zero waits:

MSAR0 = 01H Start address: 010000H

MAMR0 = 07H Address area: 64 Kbyte

WAITC0 = 83H 16-bit data bus, zero waits, address area 0 settings enabled

3.7 8-Bit Timers

The TMP95CU54A incorporates eight 8-bit timers (timers 0 to 7).

Each timer can operate independently or be cascaded to form four 16-bit timers. The 8-bit timers have the following four operating modes.

- 8-bit interval timer mode (8 channels)
 - 16-bit interval timer mode (4 channels)
 - 8-bit programmable square wave pulse generation (PPG: variable cycle, variable duty) output mode (4 channels)
 - 8-bit PWM (pulse width modulation: variable duty at fixed cycle) output mode (4 channels)
- } These modes can be combined
(for example, four 8-bit timers and two 16-bit timers).

Figure 3.7.1 shows the block diagram of 8-bit timers 0 and 1. The other 8-bit timers (timers 2 and 3, 4 and 5, and 6 and 7) have the same circuit configuration as timers 0 and 1.

Each 8-bit timer consists of an 8-bit up-counter, an 8-bit comparator, and an 8-bit timer register. One timer flip-flop each (TFF1, TFF3, TFF5, and TFF7) is provided for the timer pairs, consisting of timers 0 and 1, timers 2 and 3, timers 4 and 5, and timers 6 and 7.

Of the input clock sources for the 8-bit timers, the $\phi T1$, $\phi T4$, $\phi T16$, and $\phi T256$ internal clocks are obtained from the 9-bit internal prescaler.

The 8-bit timers are controlled by nine control registers (T01MOD, T23MOD, T45MOD, T67MOD, T02FFCR, T46FFCR, T8RUN, T16RUN, and TRDC).

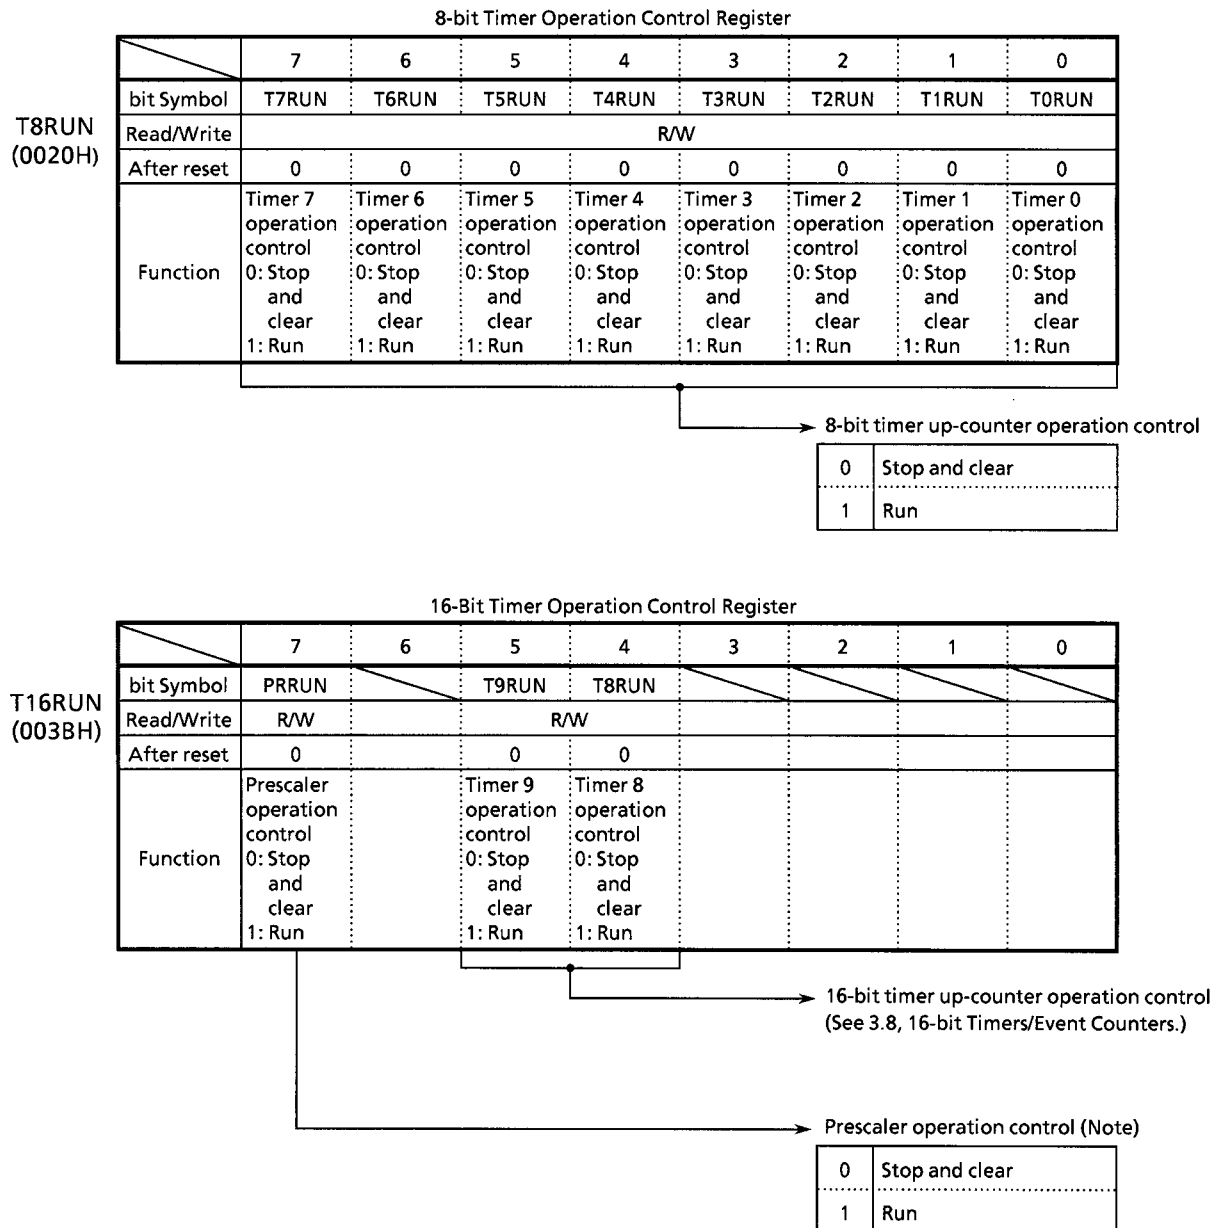

Figure 3.7.1 8-Bit Timer Block Diagram (Timers 0, 1)

3.7.1 8-Bit Timer Registers

Figure 3.7.2 shows the 8-bit timer registers. Setting these registers controls the operation of the 8-bit timers.

Note: Set T16RUN <PRRUN> to 1 when using an 8-bit timer.

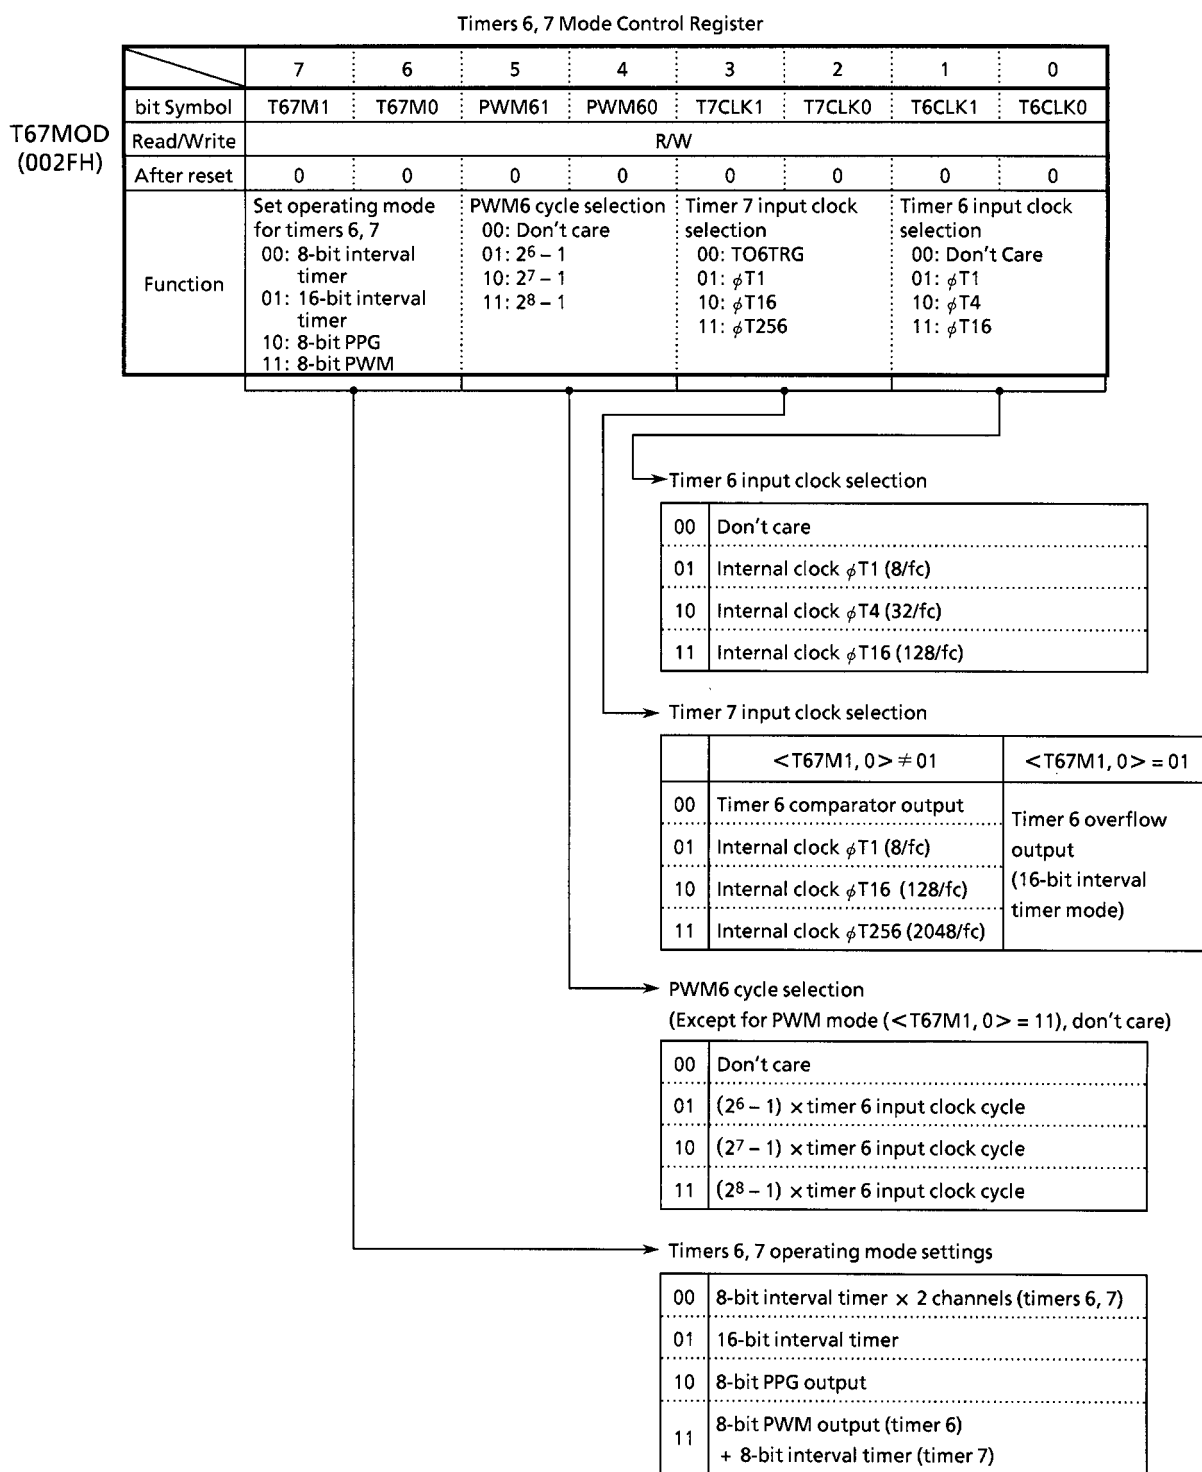

Figure 3.7.2 Register for 8-Bit Timer (6/8)

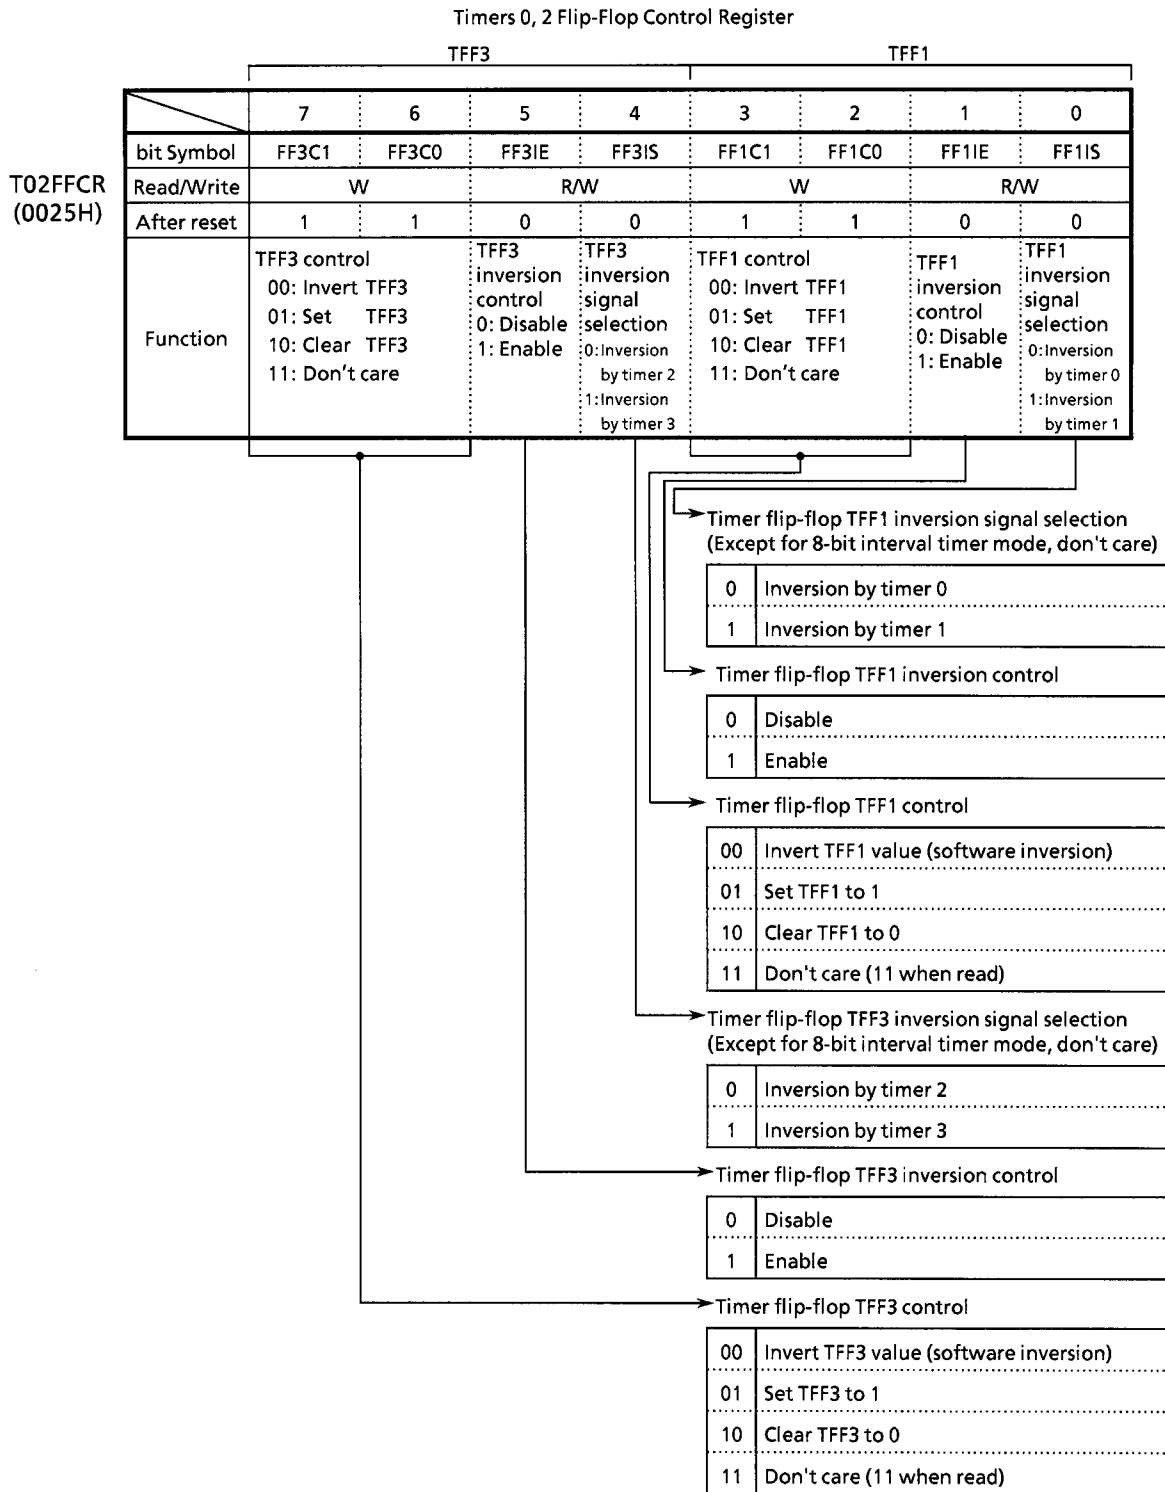

Figure 3.7.2 Register for 8-Bit Timer (7/8)

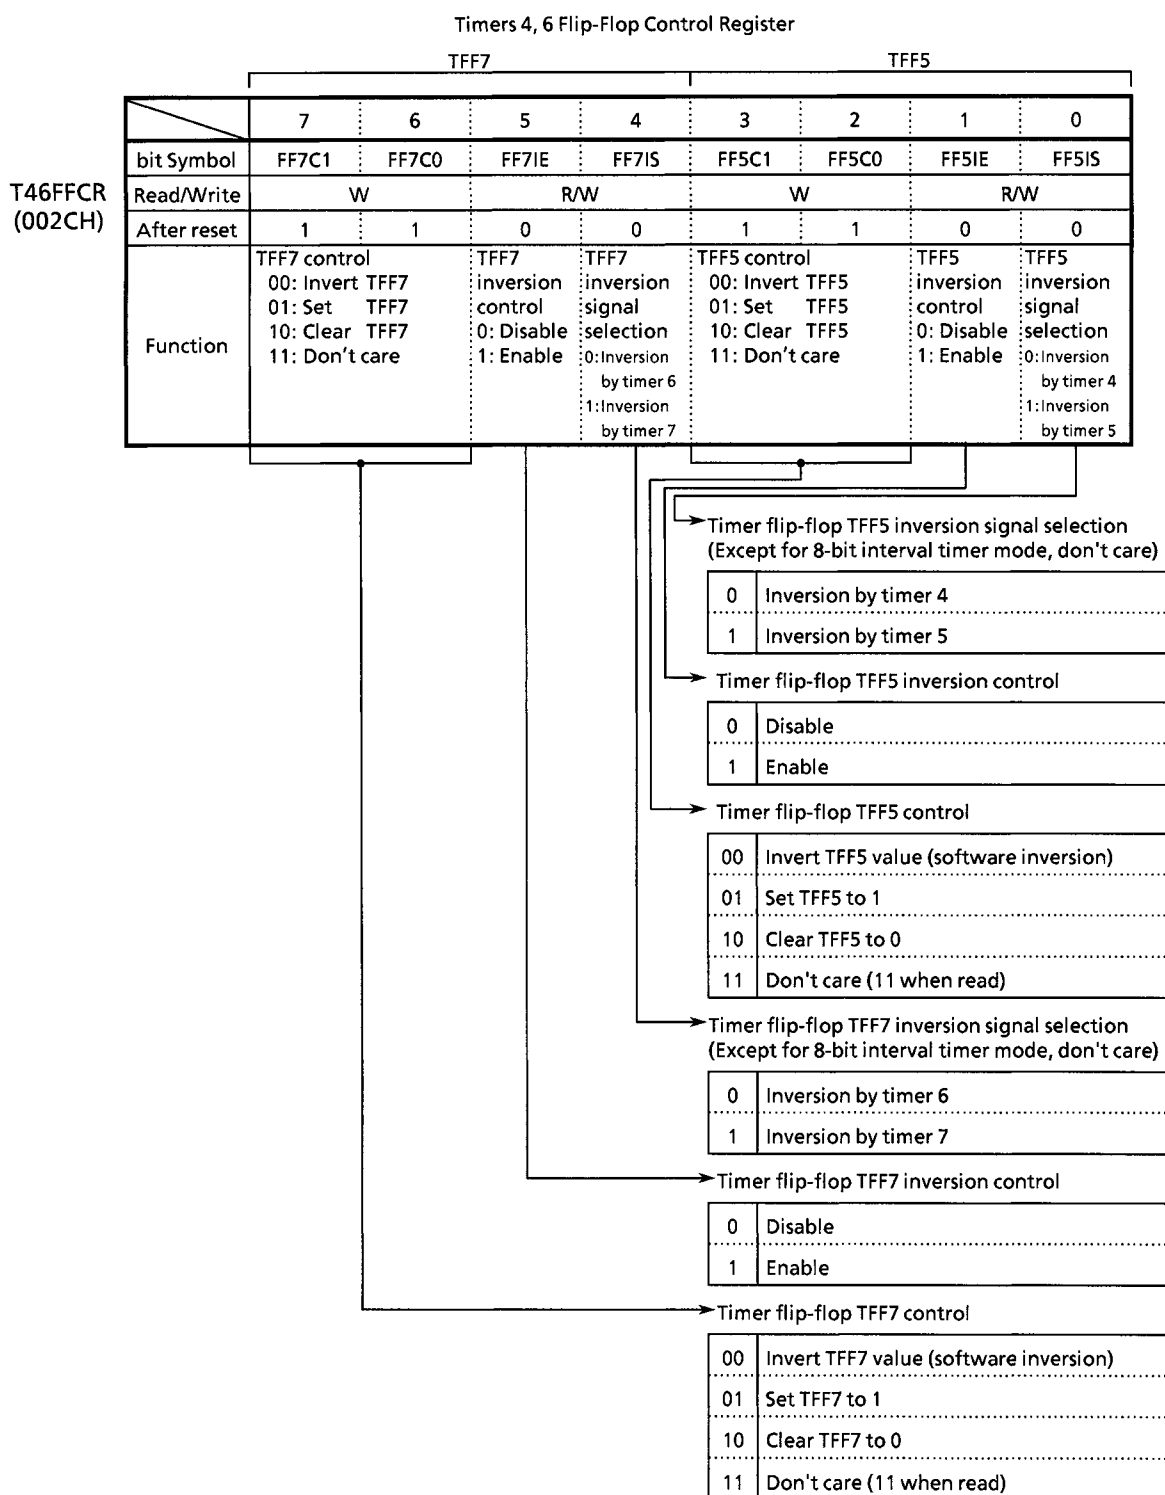

Figure 3.7.2 Register for 8-Bit Timer (8/8)

3.7.2 Block Structure

(1) Prescaler

The prescaler is a 9-bit divider circuit that divides its supplied clock ($4/f_c$) by 2^n ($n = 1, \dots, 6, 9$). The clock supplied to the prescaler is the CPU clock (f_c) divided by four ($4/f_c$). The divided clock is used as the input clock for such functions as the 8-bit timers, 16-bit timer/event counters, and baud rate generator.

The prescaler count can be turned on and off using timer operation control register T16RUN<PRRUN>. Setting T16RUN<PRRUN> to 1 starts the count.

Setting 0 clears the divided clock to zero and stops the prescaler. A reset clears <PRRUN> to 0, clearing and stopping the prescaler.

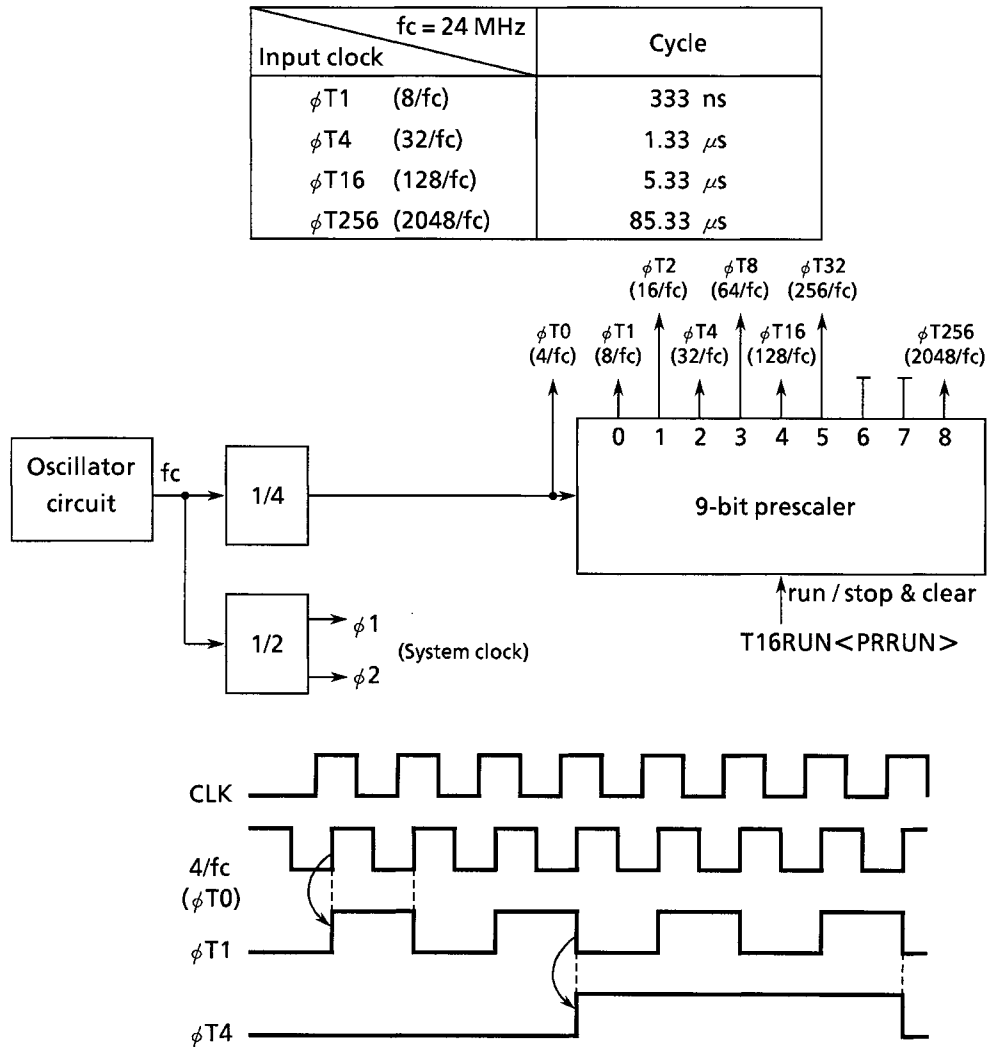

Figure 3.7.3 Prescaler

(2) 8-bit up-counters

The 8-bit up-counters UC0 to 7 are the 8-bit binary counters for timers 0 to 7. The up-counters count up on the internal or external clock selected by 8-bit timer mode control registers T01MOD, T23MOD, T45MOD, and T67MOD. The 8-bit timer operation control register T8RUN settings control the up-counter operation.

The available input clocks for UC0, 2, 4, 6 are the internal clocks $\phi T1$, $\phi T4$, or $\phi 16$. UC0 and 4 can use the external clocks input from the timer input pin (TI0 and TI4) signals.

The input clocks for UC1, 3, 5, 7 vary according to the operating mode.

In 16-bit timer mode, the overflow output signals of timer 0, 2, 4, 6 are used as the input clocks.

In other than 16-bit timer mode, the available input clocks are internal clocks $\phi T1$, $\phi T16$, $\phi T256$ or TOxTRG (timer 0, 2, 4, 6 match detect signals).

A reset clears T8RUN and stops UC0 to 7.

(3) 8-bit timer registers

The 8-bit timer registers are 8-bit registers for setting count values.

The comparator outputs a match detect signal when the value set in 8-bit timer register TREG0 to 7 matches the 8-bit up-counter UC0 to 7 value. If 00H is set, the match detect signal is output when the 8-bit up-counter overflows.

8-bit timer registers TREG0, 2, 4, 6 have a double-buffer configuration (each has a dedicated register buffer).

Timer register double-buffer control registers TRDC<TR0/2/4/6DE> enable or disable the double buffer. Setting <TR0/2/4/6DE> to 0 disables the double-buffer; setting <TR0/2/4/6DE> to 1 enables the double buffer.

When the double buffer is enabled, data are transferred from the register buffer to the timer register at a $2^n - 1$ overflow in pulse width modulation (PWM) mode, or at a cycle compare match in programmable pulse generation (PPG) mode.

Always disable the double buffer in 8-bit and 16-bit interval timer modes.

A reset clears TRDC to 0 and disables the double buffer. When using the double buffer, first write data to TREG0, 2, 4, 6 and set TRDC<TR0/2/4/6DE> to 1, then write the next settings.

As TREG0 to 7 are undefined after a reset, set the registers before using the 8-bit timers.

Figure 3.7.4 shows the configuration of timer registers 0, 2, 4, 6.

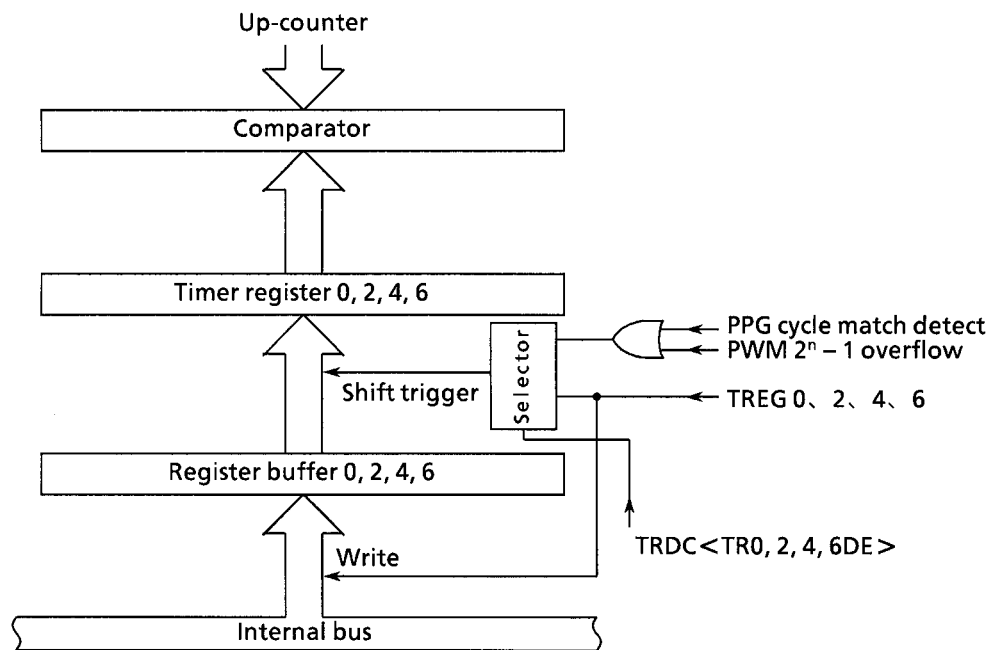

Figure 3.7.4 Configuration of Timer Registers 0, 2, 4, 6

Note: The timer register and register buffer are allocated to the same address in memory. When TRDC<TR0/2/4/6DE> is set to 0, the same value is written to both the register buffer and the timer register. When TRDC<TR0/2/4/6DE> is set to 1, the value is written to the register buffer only. Accordingly, when writing the initial values to the timer registers, first disable the register buffers.

The timer registers are located in memory as follows.

TREG0	TREG1	TREG2	TREG3
8 bits	8 bits	8 bits	8 bits
000022H	000023H	000026H	000027H
TREG4	TREG5	TREG6	TREG7
8 bits	8 bits	8 bits	8 bits
000029H	00002AH	00002DH	00002EH

All registers are write-only and therefore cannot be read.

(4) 8-bit comparator

The 8-bit comparator compares the 8-bit up-counter value with the 8-bit timer register value and detects when the values are equal (match). If the values match, a match detect signal is output, the 8-bit up-counter is cleared to zero, and an interrupt is generated (INTT0 to 7).

(5) Timer flip-flops

The timer flip-flops (TFF1, TFF3, TFF5, TFF7) are inverted by a match detect signal from the 8-bit comparator.

Timer flip-flop control registers T02FFCR<FF3IE>, <FF1IE>, and T46FFCR <FF7IE>, <FF5IE> enable or disable inversion. Setting these bits to 0 disables inversion; setting to 1 enables inversion.

The timer flip-flop values after a reset are undefined. Writing 01 or 10 to T02FFCR<FF3C1, 0>, <FF1C1, 0>, or T46FFCR<FF7C1, 0>, <FF5C1, 0> sets the timer flip-flop to 0 or 1. Writing 00 to the bits inverts the timer flip-flop value (software inversion).

The TFF1, TFF3, TFF5, and TFF7 values can be output to the timer output pins TO1 (shared with P71), TO3 (shared with P72), TO5 (shared with P74), and TO7 (shared with P75) respectively.

As the timer output pins also function as P71, P72, P74, and P75, be sure to set the port 7 function register P7FC before performing timer output.

(See Figure 3.5.26 Register for Port 7)

3.7.3 Operation Description for Each Mode

(1) 8-bit interval timer mode

The eight interval timers 0 to 7 can be used independently. When setting the functions and count data, first stop timers 0 to 7.

The following describes the example of timer 1 only.

[1] Generate interrupts at fixed intervals

Use T01MOD to select the operating mode and input clock. Set the interval time (cycle) in TREG1. Enable interrupt INTT1 such that INTT1 is generated when a match occurs between UC1 and TREG1. After setting the registers, start the timer counting.

Table 3.7.1 shows the input clock selection.

Example: To generate a timer 1 interrupt every 33 μ s (at $f_c = 24$ MHz), set the registers in the following order:

		MSB				LSB				
		7	6	5	4	3	2	1	0	
T8RUN	←	-	-	-	-	-	-	0	-	Stop timer 1 and clear to zero.
T01MOD	←	0	0	X	X	0	1	-	-	Set 8-bit interval timer mode and set input clock to ϕ T1 (0.33 μ s @fc = 24 MHz).
TREG1	←	0	1	1	0	0	1	0	0	Set 33 μ s $\div \phi$ T1 = 100 (64H) in timer register.
INTET01	←	1	1	0	1	-	-	-	-	Enable INTT1 and set interrupt level to 5.
T16RUN	←	1	X	-	-	X	X	X	X	
T8RUN	←	-	-	-	-	-	-	1	-	Start timer 1 counting.

Note: X : Don't care - : No change

Table 3.7.1 Selecting Interval and Input Clock for 8-Bit Timer Interrupt

Input Clock	Interrupt Interval (@ $f_c = 24$ MHz)	Resolution
ϕ T1 (8/ f_c)	0.33 μ s to 85.33 μ s	0.33 μ s
ϕ T4 (32/ f_c)	1.33 μ s to 341.3 μ s	1.33 μ s
ϕ T16 (128/ f_c)	5.33 μ s to 1.365 ms	5.33 μ s
ϕ T256 (2048/ f_c)	85.33 μ s to 21.85 ms	85.33 μ s

[2] Generate square wave with 50%-duty cycle

To output a square wave with a duty cycle of 50%, set a count value equivalent to half the desired cycle and TFF1 to invert on a match detect signal from timer 1 (T02FFCR<FF1IE, FF1IS> = 11).

Also, set P71 as a timer output (P7CR<P71C> = 1, P7FC<P71F> = 1)

Example: To output a square wave from pin TO1 with an interval of 2 μs (at $f_c = 24\text{ MHz}$), set the registers in the following order:

		MSB						LSB	
		7	6	5	4	3	2	1	0
T8RUN	←	-	X	-	-	-	-	0	-
T01MOD	←	0	0	X	X	0	1	-	-
TREG1	←	0	0	0	0	0	0	1	1
T02FFCR	←	-	-	-	-	1	0	1	1
P7CR	←	X	X	-	-	-	-	1	-
P7FC	←	X	X	-	-	X	-	1	X
T16RUN	←	1	X	-	-	X	X	X	X
T8RUN	←	-	-	-	-	-	-	1	-

Stop timer 1 and clear to zero.

Set 8-bit interval timer mode and set input clock to ϕ T1.

Set $2\mu\text{s} \div \phi\text{T1}$ ($0.33\mu\text{s}$) $\div 2 = 3$ in timer register.

Clear TFF1 to 0 and set to invert on match detect signal from timer 1.

} Set P71 as TO1 pin.

Start timer 1 counting.

Note: X : Don't care - : No change

Figure 3.7.5 Square Wave (50% Duty Cycle) Output Timing Chart

- [3] To count up at each timer 0 match output, set timer 1

Set 8-bit timer mode and the timer 0 comparator output as the timer 1 input clock (T01MOD<T1CLK1, 0> = 00).

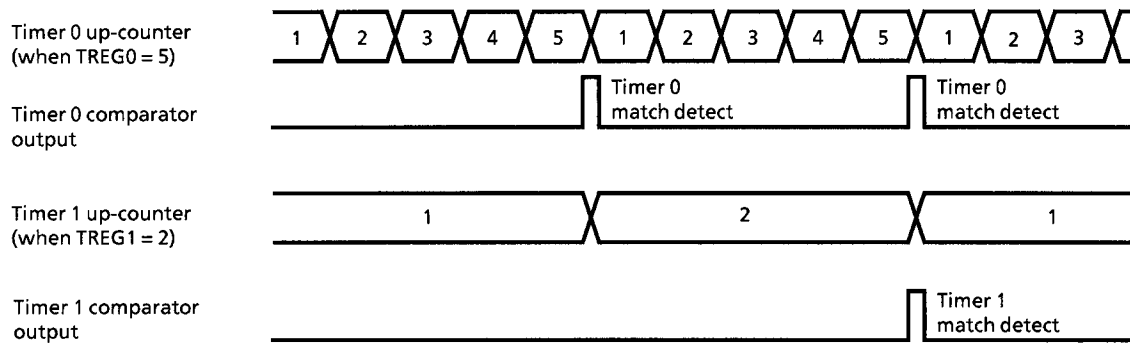

Figure 3.7.6 Using Timer 0 to Drive Timer 1 Count

(2) 16-bit interval timer mode

The 8-bit timers can be cascaded in pairs (timers 0 and 1, 2 and 3, 4 and 5, 6 and 7) to create 16-bit interval timers.

Timers 0 and 1, 2 and 3, 4 and 5, 6 and 7 operate the same. Each pair can be used independently.

The following describes the example of timers 0 and 1.

To cascade timers 0 and 1 to form a 16-bit interval timer, set the timer 0, 1 mode control register T01MOD<T01M1, 0> to 01.

When 16-bit interval timer mode is set, the T01MOD<T1CLK1, 0> setting is ignored and the timer 0 overflow output is forcibly set as the timer 1 input clock.

Table 3.7.2 shows the relationship between the timer (interrupt) interval and the input clock selection.

Table 3.7.2 16-Bit Timer (Interrupt) Interval and Input Clock Selection

Input Clock	Interrupt Interval (fc = 24 MHz)	Resolution
$\phi T1$ (8/fc)	0.33 μs to 21.845 ms	0.33 μs
$\phi T4$ (32/fc)	1.33 μs to 87.381 ms	1.33 μs
$\phi T16$ (128/fc)	5.33 μs to 349.525 ms	5.33 μs

To set the timer interrupt interval, set the lower eight bits in timer register TREG0 and the upper eight bits in TREG1. Be sure to set TREG0 first (as entering data in TREG0 temporarily disables compare, while entering data in TREG1 starts compare).

Example: To generate interrupt INTT1 every 0.33s at $f_c = 24$ MHz, set the following values in timer registers TREG0 and TREG1:

Using $\phi T16$ ($= 5.33 \mu s$ @ 24 MHz) as a timer input clock

$$0.33 \text{ s} \div 5.33 \mu s = 62500 = F424H$$

Therefore, set TREG1 to F4H, and TREG0 to 24H.

Whenever 8-bit up-counter UC0 and TREG0 match, the timer 0 comparator outputs a match detect signal, but up-counter UC0 is not cleared. No INTT0 interrupt is generated.

When up-counter UC1 and TREG1 match, at comparator timing the timer 1 comparator outputs a match detect signal.

When comparator match detect signals for both timer 0 and timer 1 are output at the same time, up-counter 0 and up-counter 1 are cleared to 0 and interrupt INTT1 only is generated. When the timer flip-flop inversion is enabled, the value of timer flip-flop TFF1 is inverted.

Table 3.7.3 Differences Between 16-Bit Timer Mode and 8-Bit Timer Mode
(Timer 1 Input Clock: TO0TRG)

	Timer 0			Timer 1		
	INTT0 interrupt	TO1 output	Counter operation when match detected	INTT1 interrupt	TO1 output	Counter operation when match detected
16-bit timer mode (count-up timer 1 on each timer 0 overflow)	No interrupt generated	Output disabled (of a signal indicating a match with TREG0 is disabled)	TREG0 count-up even when a match occurs. Clear at match with TREG1	Interrupt generated	Output enabled (can output a match signal for both timers 0 and 1)	$TREG1 \times 2^8 + TREG0$: Full 16 bits (clear at match)
8-bit timer mode (count up timer 1 on each timer 0 match)	Interrupt generated	Output enabled (either from timer 0 or timer 1)	TREG0 (clear at match)	Interrupt generated	Output enabled (either from timer 0 or timer 1)	$TREG1 \times TREG0$: Multiplication value (clear at match)

Example: When TREG1 = 04H and TREG0 = 80H:

Figure 3.7.7 Timer Output for 16-Bit Timer Mode

(3) 8-bit programmable pulse generation (PPG) output mode

Timers 0, 2, 4, or 6 can output square waves with variable frequencies and variable duty (programmable pulse generation). The output pulse can be set to either active low or active high. Timers 1, 3, 5, and 7 cannot be used in this mode.

Timer 0 outputs from pin TO1 (shared with pin P71), timer 2 outputs from pin TO3 (shared with pin P72), timer 4 outputs from TO5 (shared with pin P74), and timer 6 outputs from TO7 (shared with pin P75).

The following describes the example of timer 0. (Timers 2, 4, 6 operate the same as timer 0.)

A programmable square wave can be output from pin TO1 by setting 8-bit programmable square wave output mode and enabling inversion of the timer flip-flop TFF1.

The TFF1 value is inverted by a match between 8-bit up-counter UC0 and TREG0, and by a match with TREG1. UC0 is cleared by a match with TREG1.

In PPG mode, timer 1 cannot be used, but timer 1 up-counter UC1 must be run ($T8RUN < T1RUN = 1$).

Also, the TREG0 and TREG1 settings in PPG mode must satisfy the following condition.

$$(TREG0 \text{ setting value}) < (TREG1 \text{ setting value})$$

Figure 3.7.8 8-Bit PPG Output Waveform

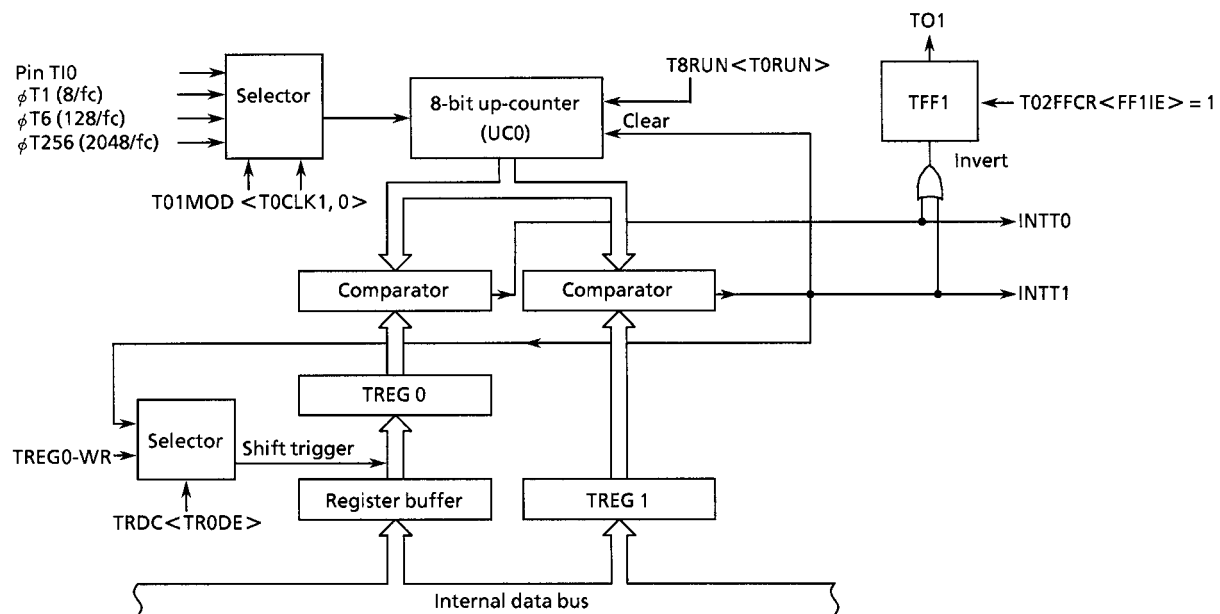

Figure 3.7.9 Block Diagram of 8-Bit PPG Output Mode

Enabling the timer register TREG0 double buffer in this mode shifts the register buffer value to TREG0 when timer register TREG1 matches 8-bit up-counter UC0.

Using the double buffer facilitates handling of small duty waves (when changing the duty).

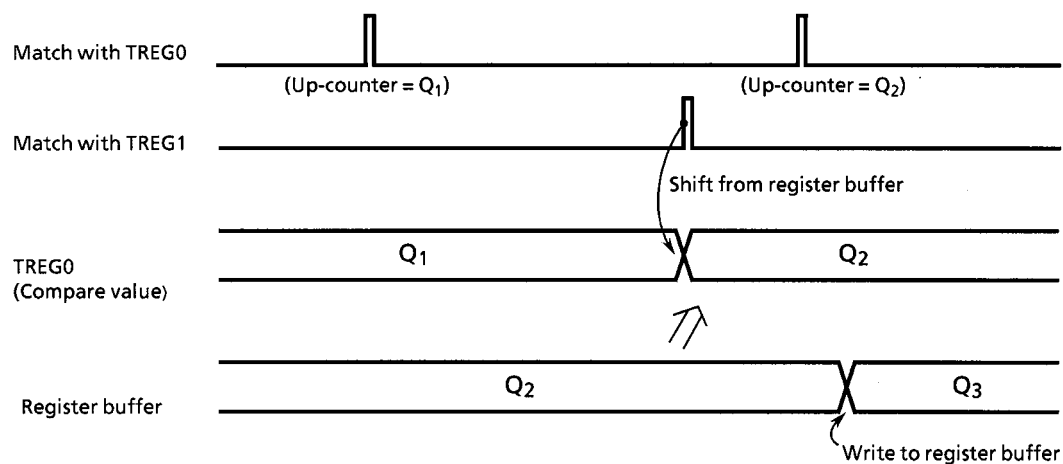

Figure 3.7.10 Register Buffer Operation

Example: Output 1/4-duty 75 kHz-pulse (@ $f_c = 24$ MHz)

Calculate the setting of the timer register.

Setting the frequency to 75 kHz creates a square wave with a cycle of $t = 1/75$ kHz = 13.3 μ s.

Using $\phi T1 = 0.33$ μ s (@ $f_c = 24$ MHz) results in

$$13.3 \mu\text{s} \div 0.33 \mu\text{s} = 40$$

Accordingly, set TREG1 = 40 = 28H.

Next, set the duty to 1/4 as follows:

$$t \times 1/4 = 13.3 \mu\text{s} \times 1/4 = 3.3 \mu\text{s}$$

As with TREG1,

$$3.3 \mu\text{s} \div 0.33 \mu\text{s} = 10$$

Accordingly, set TREG0 = 10 = 0AH.

(4) 8-bit pulse width modulation (PWM) output mode

Only timers 0, 2, 4, 6 can be set to this mode, which allows up to four pulse width modulation outputs with 8-bit resolution. Timers 1, 3, 5, and 7 can be used as 8-bit timers.

In the case of timer 0, PWM is output to pin TO1 (shared with P71). In the case of timers 2, 4, 6, PWM is output to pins TO3 (shared with P72), TO5 (shared with P74), and TO7 (shared with P75) respectively.

Here, the example of timer 0 is used. (Timers 2, 4, 6 operate the same as timer 0.)

Timer output inversion occurs when the 8-bit up-counter UC0 setting and the timer register TREG0 setting match, or when $2^n - 1$ (T01MOD specifies one of $n = 6$, $n = 7$, or $n = 8$) counter overflow occurs. UC0 is cleared by the $2^n - 1$ counter overflow.

In addition, the following conditions must be satisfied when using 8-bit PWM output mode:

(Timer register setting) < ($2^n - 1$ counter overflow setting)

(Timer register setting) $\neq 0$

Figure 3.7.11 8-Bit PWM Output Waveform

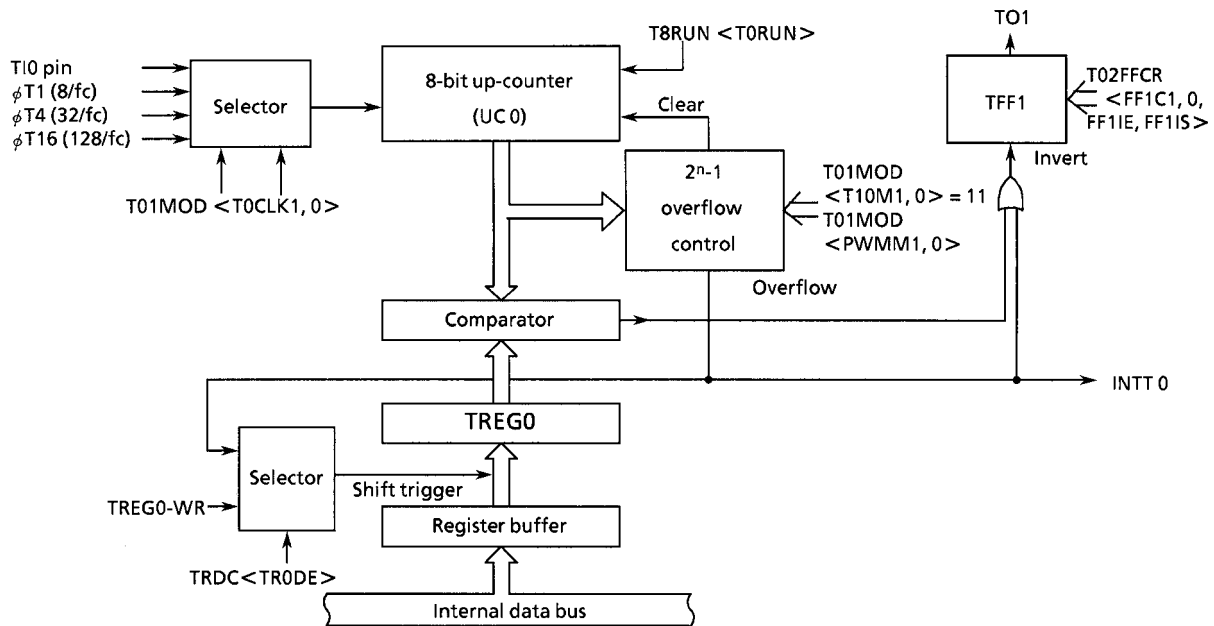

Figure 3.7.12 Block Diagram of 8-Bit PWM Output Mode

Enabling the TREG0 double-buffer in this mode shifts the register buffer value to TREG0 when $2^n - 1$ counter overflow is detected.

Using the double buffer facilitates handling of small duty waves.

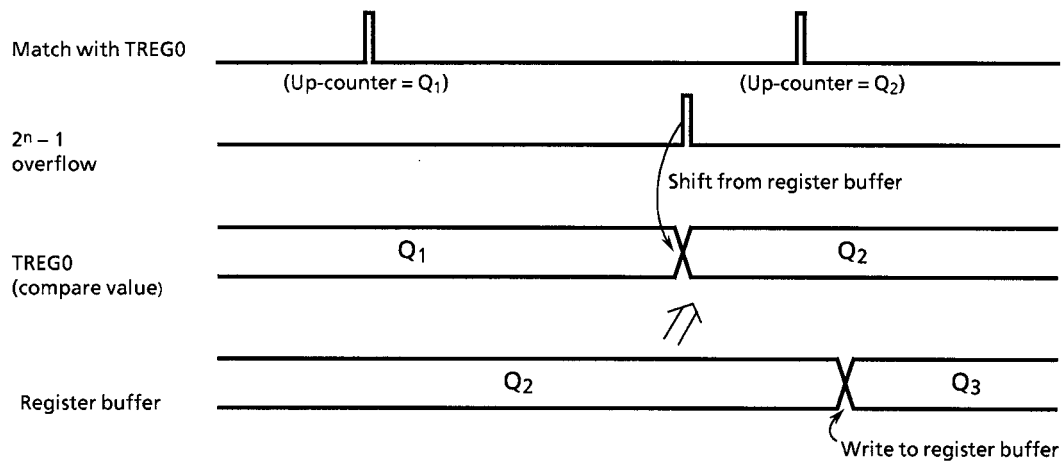

Figure 3.7.13 Register Buffer Operation

Example: Output following PWM waveform to pin TO1 (@ $f_c = 24$ MHz)

To realize a PWM interval of $42.33 \mu s$ using $\phi T1 = 0.33 \mu s$ (@ $f_c = 24$ MHz):

$$42.33 \mu s \div 0.33 \mu s = 127 = 2^n - 1$$

Accordingly, set $n = 7$.

As the low level cycle is $30 \mu s$, at $\phi T1 = 0.33 \mu s$,

$$30 \mu s \div 0.33 \mu s = 90$$

Accordingly, set $TREG0 = 90 = 5AH$.

	MSB	7	6	5	4	3	2	1	0	LSB	
T8RUN	←	-	-	-	-	-	-	-	0		Stop timer 0 and clear to 0.

Note: External clock is not input to timer 2 or timer 6.

3.8 16-Bit Timers/Event Counters

The TMP95CU54A incorporates two multi-function 16-bit timer/event counters (timers 8 and 9). Timers 8 and 9 have the same functions and can operate independently. The 16-bit timers have the following three operating modes.

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable pulse generation (PPG) output mode

The capture function can also be used to perform the following operations.

- One-shot pulse output from the external trigger pulse
- Frequency measurement
- Pulse width measurement
- Time differential measurement

Also, the 16-bit timers can be used to output a signal with any phase difference.

Figure 3.8.1 is a block diagram of the 16-bit timer/event counters (timer 8). Timer 9 has the same circuit configuration.

Each 16-bit timer/event counter consists of a 16-bit up-counter, a 16-bit comparator, a 16-bit timer register, and a 16-bit capture register. Timers 8 and 9 each have two timer flip-flops (TFF8/9 and TFFA/B).

Clock sources $\phi T1$, $\phi T4$, and $\phi T16$ input to the 16-bit timers are obtained from the internal 9-bit prescaler (see 3.7.2 (1), Prescaler).

The 16-bit timer/event counters are controlled by six control registers (T8MOD, T9MOD, T8FFCR, T9FFCR, T16RUN, and T89CR).

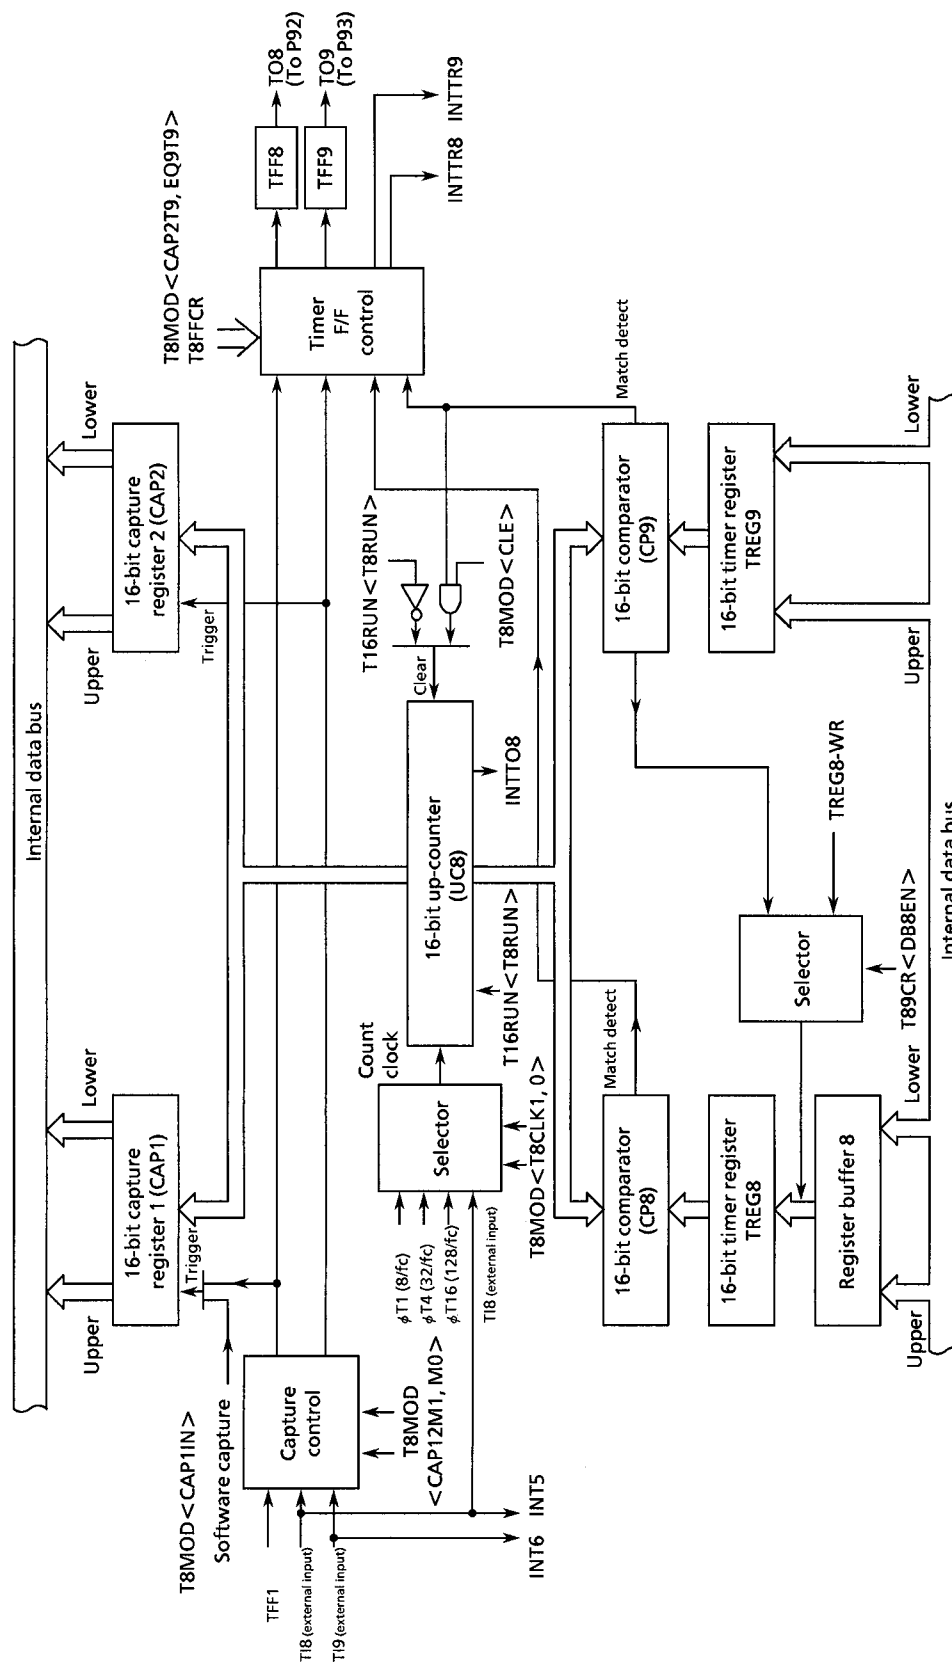

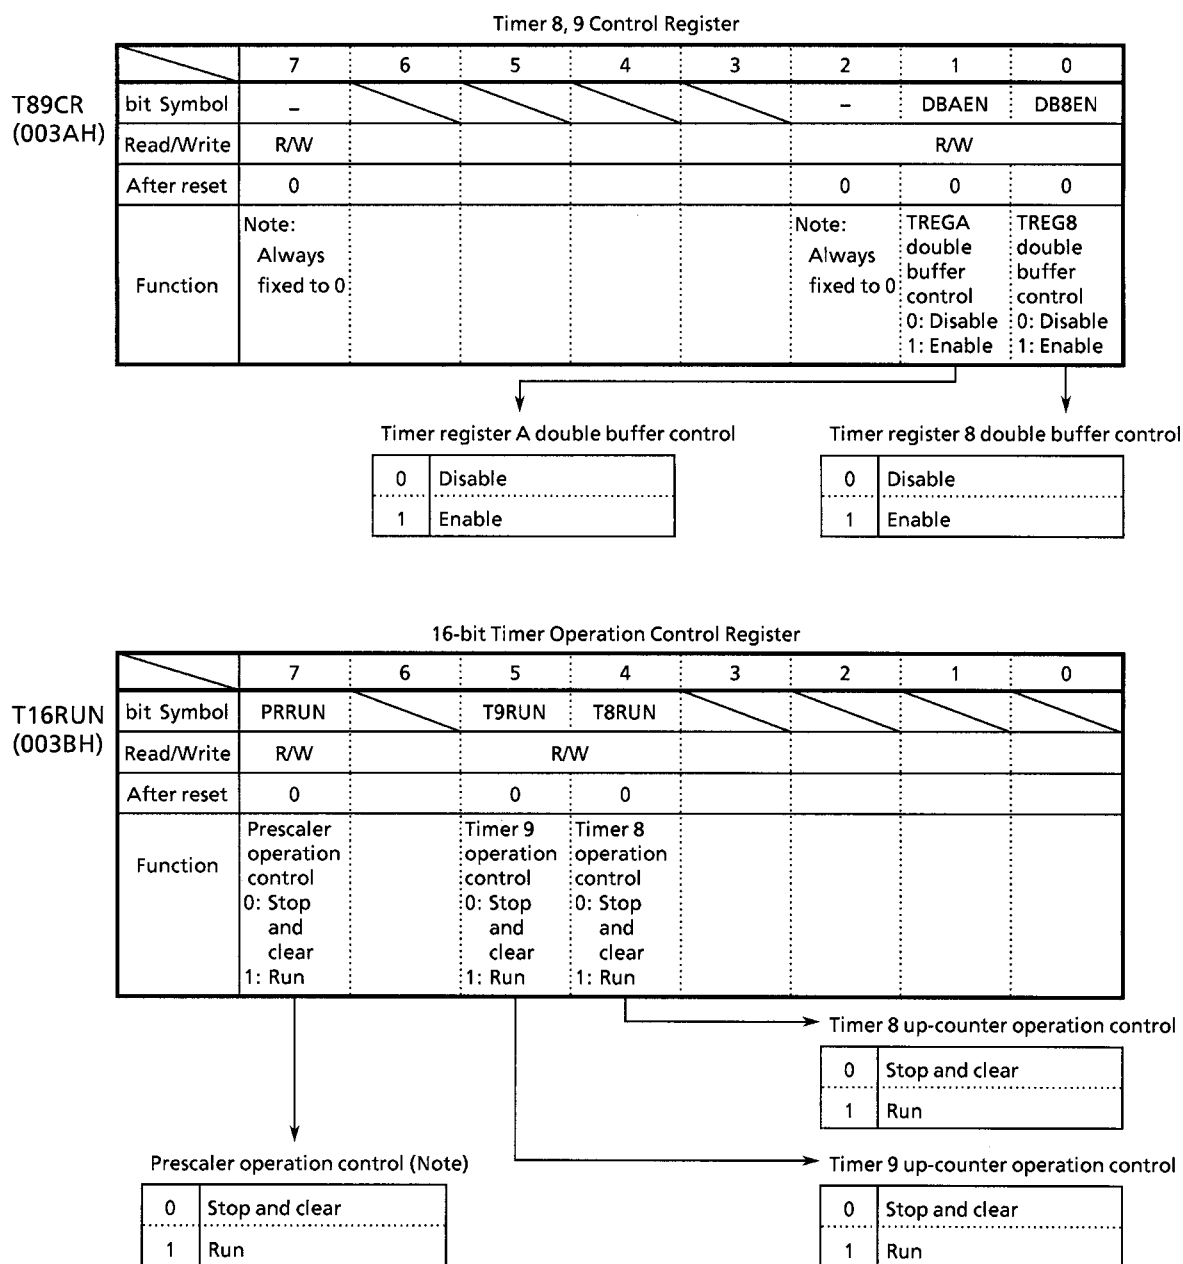

Figure 3.8.1 16-Bit Timer Block Diagram (Timer 8)

3.8.1 16-Bit Timer/Event Counter Registers

Figure 3.8.2 shows the 16-bit timer/event counter related registers.

These register settings control the 16-bit timer/event counter operations.

Note: When running a 16-bit timer, set T16RUN <PRRUN> to 1.

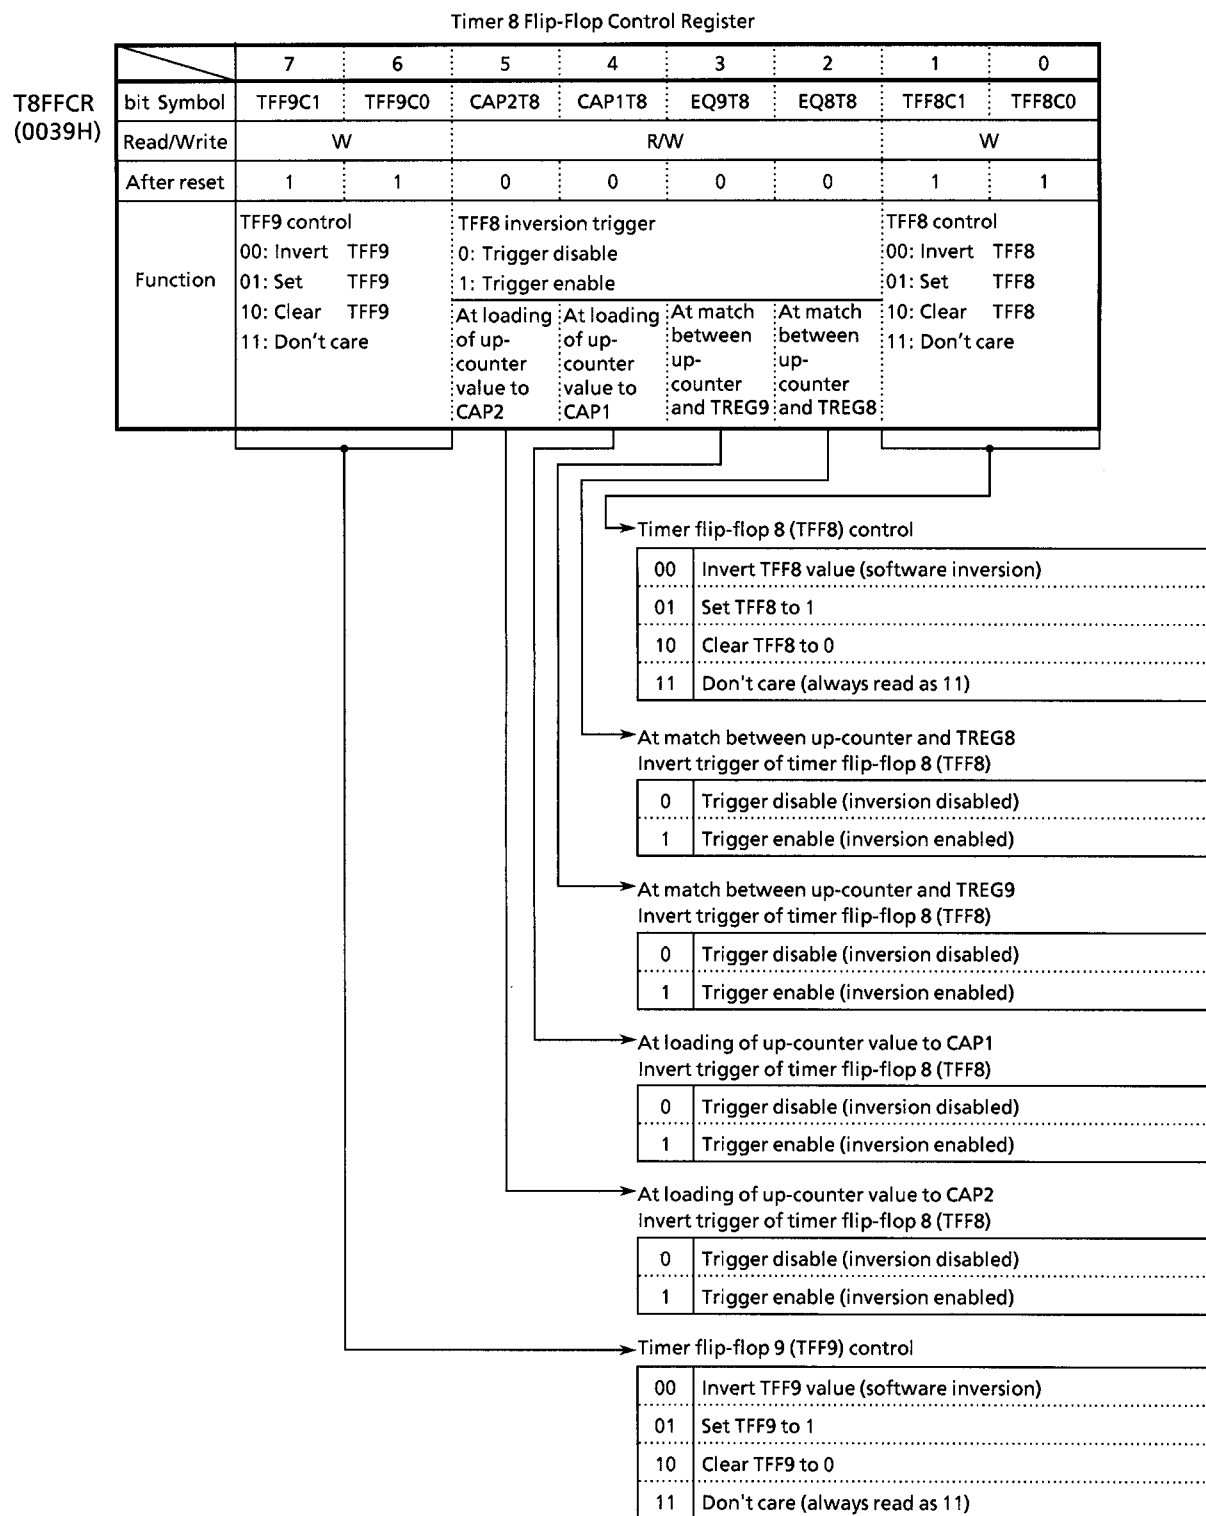

Figure 3.8.2 16-Bit Timer/Event Counter Related Register (3/5)

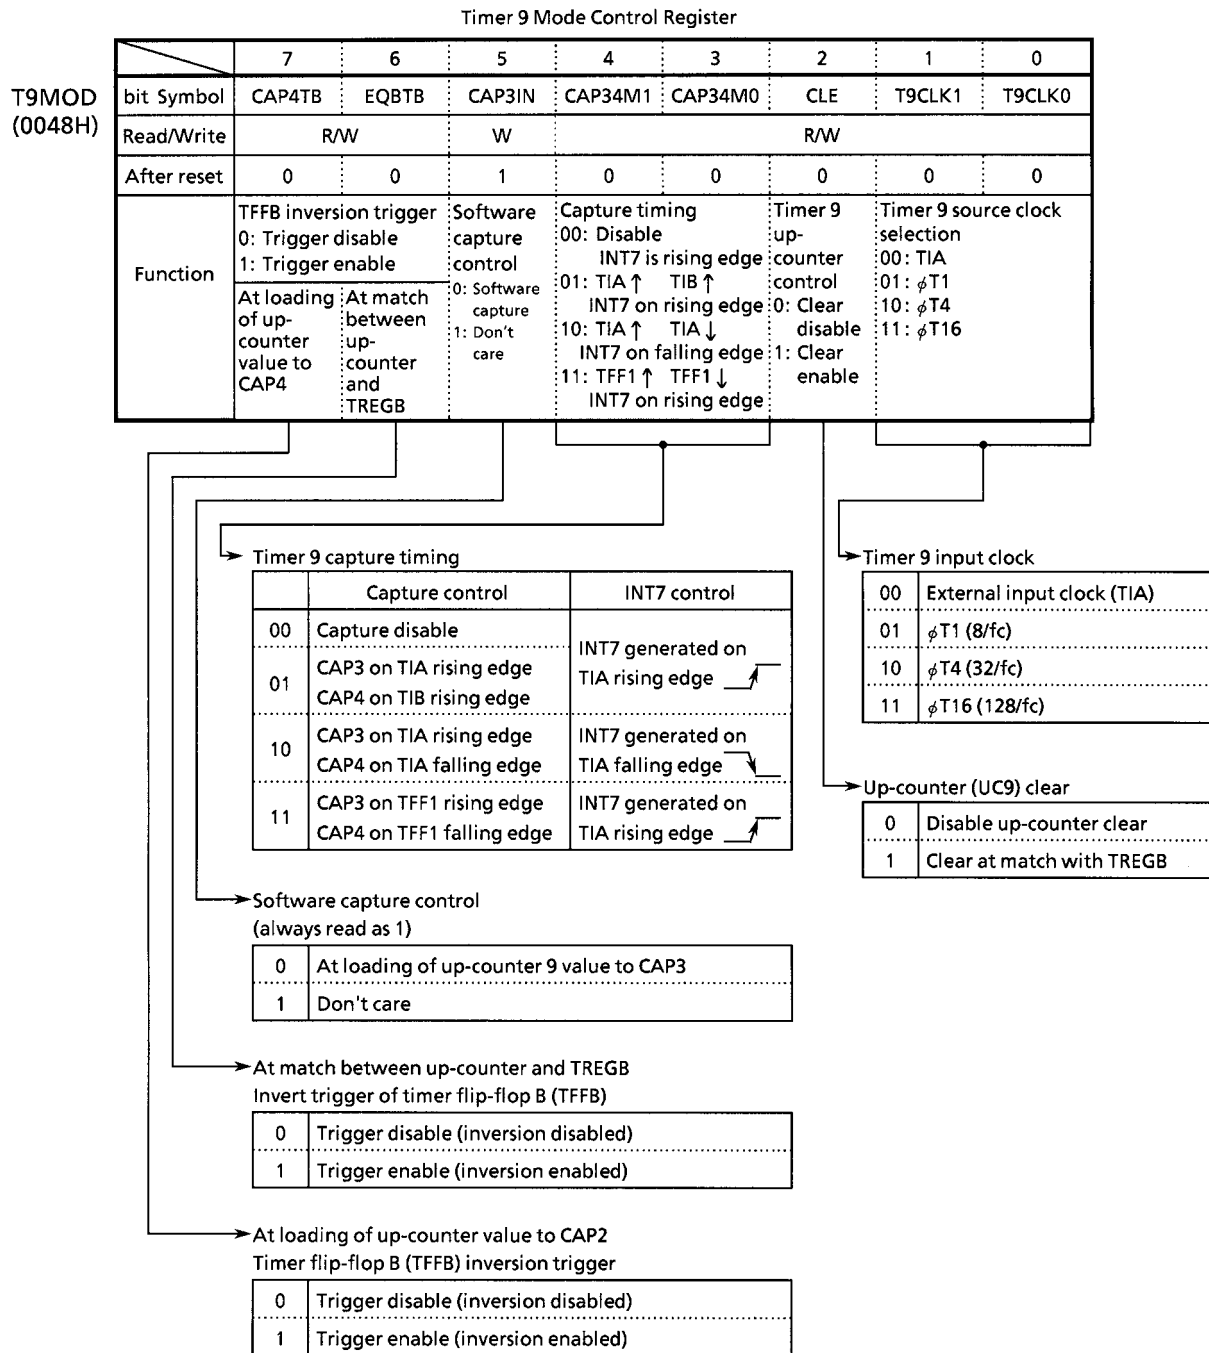

Figure 3.8.2 16-Bit Timer/Event Counter Related Register (4/5)

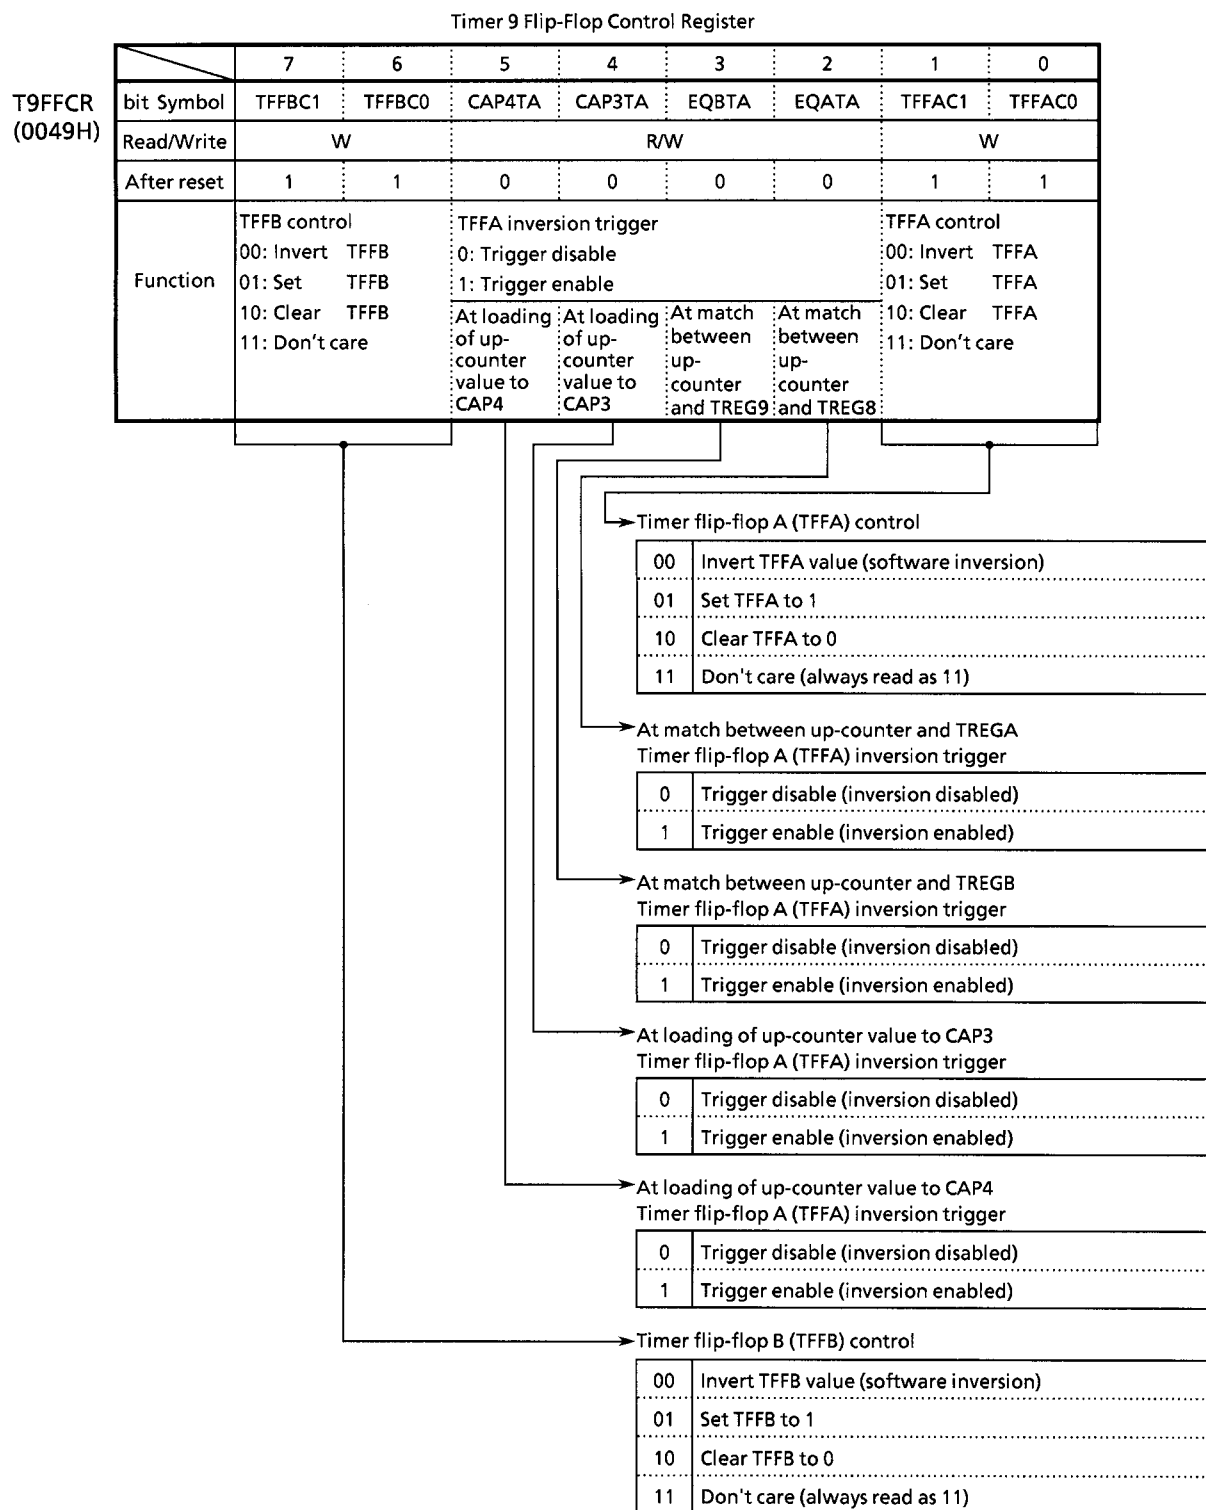

Figure 3.8.2 16-Bit Timer/Event Counter Related Register (5/5)

3.8.2 Block Structure

(1) 16-bit up-counters

16-bit up-counters UC8 and 9 are 16-bit binary counters for timers 8 and 9.

These up-counters count up on the external and internal clocks selected by 16-bit timer mode control registers T8MOD and T9MOD. To control the up-counter operations, use 16-bit timer operation control register T16RUN.

The UC8, 9 input clock is selected from either internal clocks $\phi T1$, $\phi T4$, and $\phi T16$, or the external clocks input from the timer input pin (TI8 and TI9).

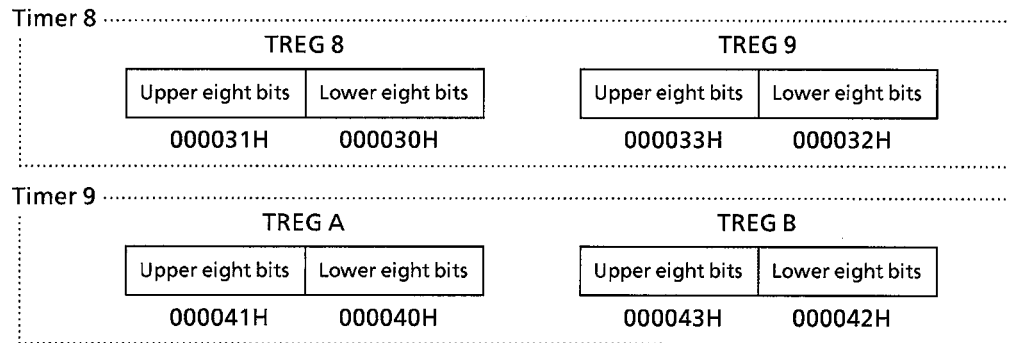

Any overflow from UC8 or 9 triggers interrupt request INTTO8 or INTTO9.

At a reset, T16RUN is cleared, and the prescaler and UC8, 9 are stopped.

(2) 16-bit timer registers

Each timer has two internal 16-bit timer registers for setting counters. A match between these timer register settings and the value of the 16-bit up-counter UC8, 9 outputs a comparator match detect signal.

Data set to 16-bit timer registers TREG8, TREG9 and TREGA, TREGB use a 2-byte data transfer instruction, or two 1-byte data transfer instructions; first for the lower eight bits, then for the upper eight bits.

TREG8 to TREGB are write-only registers and therefore cannot be read.

Of the 16-bit timer registers, TREG8 and TREGA have a double-buffer configuration (each has a register buffer).

Timer 8, 9 control register T89CR<DB8EN, DBAEN> enables/disables the double buffer. Setting <DB8EN, DBAEN> to 0 disables the double buffer; setting <DB8EN, DBAEN> to 1 enables the double buffer.

With the double buffer enabled, data are transmitted from the register buffer to the timer register at a match between up-counter UC8 and TREG9, or between UC9 and timer register TREGB.

As TREG8 to TREGB are undefined after a reset, when using a 16-bit timer write the data first.

A reset clears T89CR to 0 and disables the double buffer. When using the double buffer, write data to TREG8, TREGA, set T89CR<DB8EN, DBAEN> to 1, then write the next data to the register buffer.

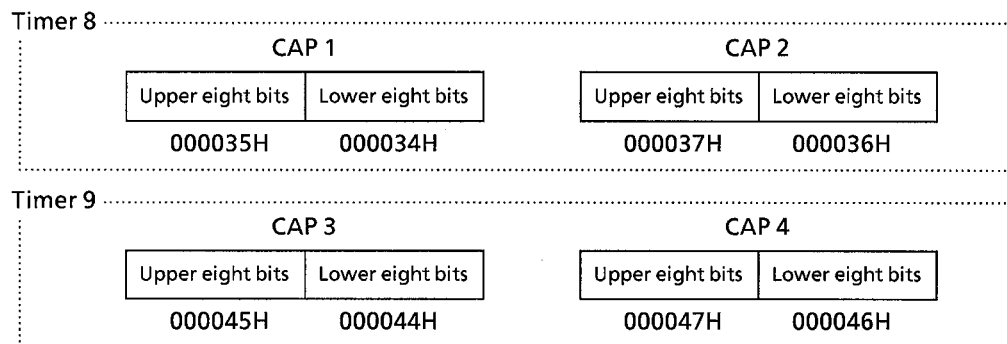

The 16-bit timer registers and register buffers are allocated to the same addresses in memory. When T89CR<DB8EN, DBAEN> is set to 0, the same value is written to the timer register and register buffer.

When <DB8EN, DBAEN> is set to 1, the value is written to the register buffer only. Therefore, the register buffer must be disabled before writing the initial value to the timer register.

(3) Capture register

The capture register is a 16-bit register for latching the 16-bit up-counter UC8, 9 value.

When reading the capture register, use a 2-byte data load instruction, or two 1-byte data load instructions; first to read the lower eight bits, then to read the upper eight bits.

CAP1 to CAP4 are read-only registers and cannot be written by software.

(4) Capture input control

The capture input control circuit controls the timing of the latching of the 16-bit up-counter UC8, 9 value to capture registers CAP1, CAP2, CAP3, and CAP4. Set the capture register latch timing with the timer 8, 9 mode control registers T8MOD<CAP12M1, 0>, T9MOD<CAP34M1, 0>.

The following describes the latch timing setting and operation.

- When T8MOD<CAP12M1, 0>, T9MOD<CAP34M1, 0> are set to 00:
The capture function is disabled. A reset also disables the capture function.
- When T8MOD<CAP12M1, 0>, T9MOD<CAP34M1, 0> are set to 01:
On the external input rising edge of TI8 (shared with P90/INT5) and TIA (shared with P94/INT7), capture register CAP1, CAP3 loads the up-counter value. On the external input rising edge of TI9 (shared with P91/INT6) and TIB (shared with P95/INT8), capture register CAP2, CAP4 loads the up-counter value. (Time differential measurement)
- When T8MOD<CAP12M1, 0>, T9MOD<CAP34M1, 0> are set to 10:
On the TI8, TIA external input rising edge, capture register CAP1, CAP3 loads the up-counter value. On the input falling edge, capture register CAP2, CAP4 loads the up-counter value. Interrupt INT4, INT6 is generated on a falling edge in this mode only. (Pulse width measurement)
- When T8MOD<CAP12M1, 0>, T9MOD<CAP34M1, 0> are set to 11:
On the timer flip-flop TFF1 rising edge, capture register CAP1, CAP3 loads the up-counter value. On the falling edge, capture register CAP2, CAP4 loads the up-counter value.
The UC8, 9 up-counter value can also be loaded to a capture register on a software request. When 0 is written to T8MOD<CAP1IN>, T9MOD<CAP3IN>, the UC8, 9 up-counter value at that time is loaded to capture register CAP1, 3.
The prescaler must first be set to RUN (set T16RUN<PRRUN> = 1).

(5) Comparator

To detect a match, the 16-bit comparator compares the 16-bit up-counter UC8, 9 with the 16-bit timer register TREG8, 9 and TREGA, B settings.

On detection of a match, the comparator outputs a match detect signal and generates interrupts INTTR8, 9 or INTTRA, B from the respective 16-bit timer.

UC8 is cleared by a match between the UC8 value and the TREG9 value. UC9 is cleared by a match between the UC9 value and the TREGB value. UC8, 9 clearing can be disabled by setting the timer 8, 9 mode control registers T8MOD<CLE>, T9MOD<CLE> to 0.

(6) Timer flip-flops

Timers 8 and 9 have two timer flip-flops each. The flip-flops of each timer have different functions.

[1] TFF8, TFFA

Flip-flops TFF8 and TFFA are inverted by a match signal from the comparator and a latch signal to the capture register.

In timer 8 and timer 9, two different capture operations and two types of match detection can be specified as inversion triggers. Use bits 2 to 5 of the T8FFCR and T9FFCR registers to set the inversion triggers.

[2] TFF9, TFFB

Timer flip-flops TFF9 and TFFB are inverted by a match signal from the comparator and a latch signal to the capture register.

In timers 8 and 9, one type of capture operation and one type of match detection can be specified as inversion triggers. Use bits 6 and 7 of the T8MOD and T9MOD registers to set the inversion triggers.

After a reset, the timer flip-flop values are undefined. Writing 01 to T8FFCR <TFF8C1, 0>, <TFF9C1, 0> or T9FFCR <TFFAC1, 0>, <TFFBC1, 0> sets the timer flip-flop to 0; writing 10 to the bits sets the timer flip-flop to 1. Writing 00 to the bits inverts the timer flip-flop value (software inversion).

The TFF8, TFF9, TFFA, and TFFB values can be output to timer output pins TO8 (shared with P92), TO9 (shared with P93), TOA (shared with P96), and TOB (shared with P96) respectively.

As the timer output pins also function as P92, P93, and P96, set port 9 function register P9FC before performing timer output. (See Figure 3.5.35 Register for Port 9)

3.8.3 Operation Description for Each Mode

(1) 16-bit interval timer mode

Interval timers 8 and 9 can be used independently as 16-bit interval timers. The following describes the example of timer 8 only.

Example: Generate interrupts at fixed intervals

To generate timer interrupts at fixed intervals, set the interval time (cycle) in 16-bit timer register TREG9 and use interrupt INTTR9.

Set the registers as follows.

	7	6	5	4	3	2	1	0		
T16RUN	←	-	X	-	0	X	X	X	X	Stop timer 8.
INTET89	←	1	1	0	0	1	0	0	0	Enable INTTR9, set interrupt level to 4, and disable INTTR8.
T8FFCR	←	1	1	0	0	0	0	1	1	Disable trigger.
T8MOD	←	0	0	1	0	0	1	*	*	Set internal clock to input clock, disable capture function, clear and enable up-counter.
										(** = 01, 10, 11)
TREG9	←	*	*	*	*	*	*	*	*	Set interval time. (16 bits)
		*	*	*	*	*	*	*	*	
T16RUN	←	1	X	-	1	X	X	X	X	Start timer 8.

Note: X : Don't care - : No change

(2) 16-bit event counter mode

Timers 8 and 9 can be set to operate as event counters by setting external inputs TI8 and TIA as the timer clock sources. The following describes timer 8 only.

The 16-bit up-counter UC8 counts up on the rising edge of the TI8 input. The count value can be read by performing a software capture and reading the capture value.

Timer input pin TI8 is shared with P90. However, there is no selection function. Therefore, event counter operation can be performed at any time by setting timer 8 to operating state. Set the registers as follows.

	7	6	5	4	3	2	1	0	
T16RUN	←	-	X	-	0	X	X	X	Stop timer 8.
P9CR	←	-	-	-	-	-	-	0	Set P90 to input mode.
INTET89	←	1	1	0	0	1	0	0	Enable INTTR9 (level 4) and disable INTTR8.
T8FFCR	←	1	1	0	0	0	0	1	Disable trigger.
T8MOD	←	0	0	1	0	0	1	0	Set input clock to TI8.
TREG9	←	*	*	*	*	*	*	*	Set number of counts (16 bits).
		*	*	*	*	*	*	*	
T16RUN	←	1	X	-	1	X	X	X	Start timer 8.

Note 1: X : Don't care - : No change

Note 2: The prescaler must also be running when using a 16-bit timer as an event counter (T16RUN<PRRUN> = 1).

(3) 16-Bit programmable pulse generation (PPG) output mode

Timers 8 and 9 can output a square wave with a user-specified frequency and duty (programmable square wave). The output pulse can be either active-low or active-high.

Timer 8 outputs a square wave from pin TO8 (shared with P92) ; timer 9, from TOA (shared with P96).

The following describes timer 8 only.

A programmable pulse (square wave) can be output from pin TO8 by triggering inversion of timer flip-flop TFF8 when a match occurs between the 16-bit up-counter UC8 and TREG8, or between UC8 and TREG9. The TREG8 and TREG9 settings must satisfy the following condition:

$$(\text{TREG8 setting}) < (\text{TREG9 setting})$$

Figure 3.8.3 16-Bit Programmable Pulse Generation (PPG) Output Waveform

Enabling the TREG8 double-buffer in this mode shifts the value of register buffer 8 to TREG8 when TREG9 matches UC8. Using the double-buffer facilitates handling of small duty waves.

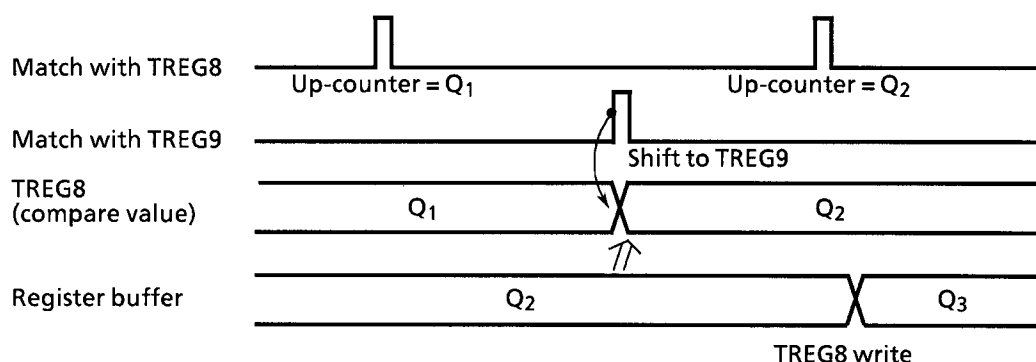

Figure 3.8.4 Register Buffer Operation

Figure 3.8.5 is a block diagram of 16-bit PPG output mode.

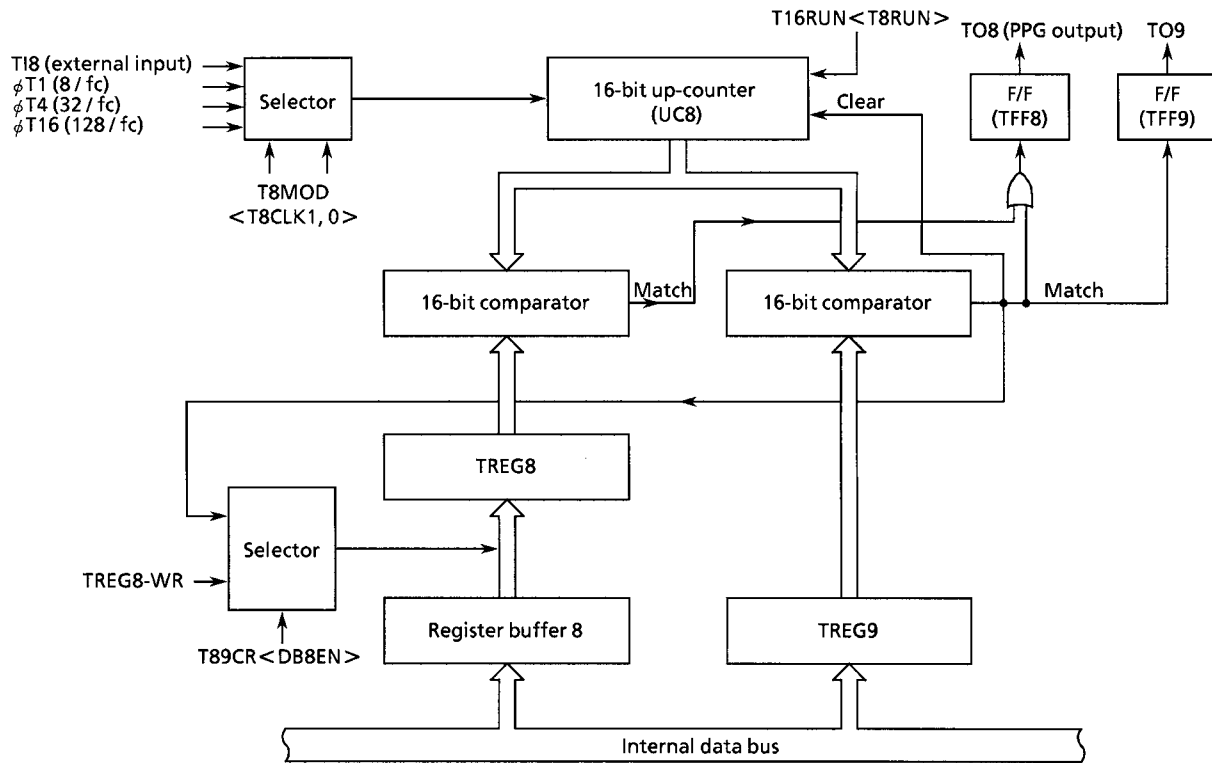

Figure 3.8.5 16-Bit PPG Output Mode Block Diagram

In 16-bit PPG output mode, set the registers as follows.

	7	6	5	4	3	2	1	0	
T16RUN	←	-	X	-	0	X	X	X	Stop timer 8.
TREG8	←	*	*	*	*	*	*	*	Set the duty. (16 bits)
		*	*	*	*	*	*	*	
TREG9	←	*	*	*	*	*	*	*	Set the interval. (16 bits)
		*	*	*	*	*	*	*	
T89CR	←	0	X	X	X	X	0	-	Enable TREG8 double-buffer
									(Duty/interval modified by INTTR9 interrupt)
T8FFCR	←	1	1	0	0	1	1	1	Set TFF8 to invert at detection of match with TREG8
									or TREG9. Set TFF8 initial value to 0.
T8MOD	←	0	0	1	0	0	1	**	Set input clock to internal clock, and disable capture
									function.
									(** = 01, 10, 11)
P9CR	←	-	-	-	-	1	-	-	} Set P92 as TO8.
P9FC	←	X	-	X	X	-	1	X	
T16RUN	←	1	X	-	1	X	X	X	Start timer 8.

Note: X : Don't care - : No change

(4) Example of capture function application

Use the capture function to realize many applications, including the following examples.

- [1] One-shot pulse output from the external trigger pulse
- [2] Frequency measurement
- [3] Pulse width measurement
- [4] Time differential measurement

The following describes these applications based on timer 8.

[1] One-shot pulse output from external trigger pulse

Obtain one-shot pulse output from the external trigger pulse as follows.

Set 16-bit up-counter UC8 to free-running count-up using an internal clock.

Input the external trigger pulse from pin TI8. Load the up-counter value to capture register CAP1 on the rising edge of the external trigger pulse using the capture function.

Interrupt INT5 is generated on the rising edge of the external trigger pulse. Add the value of capture register CAP1 at this interrupt (c) to the delay time (d), and set timer register TREG8 to the sum of these values (c + d). Add the pulse width of the one-shot pulse (p) to TREG8, and set timer register TREG9 to the result (c + d + p).

In addition, set the timer 8 flip-flop control register T8FFCR<EQ9T8, EQ8T8> to 11 and enable the trigger to invert timer flip-flop TFF8 when a match occurs between UC8 and TREG8 or UC8 and TREG9. Then, after output of the one-shot pulse, set the trigger back to disabled state during INTTR9 interrupt processing.

The (c), (d), and (p) notation above corresponds to c, d, and p in Figure 3.8.6, One-Shot Pulse Output from External Trigger Pulse (With Delay).

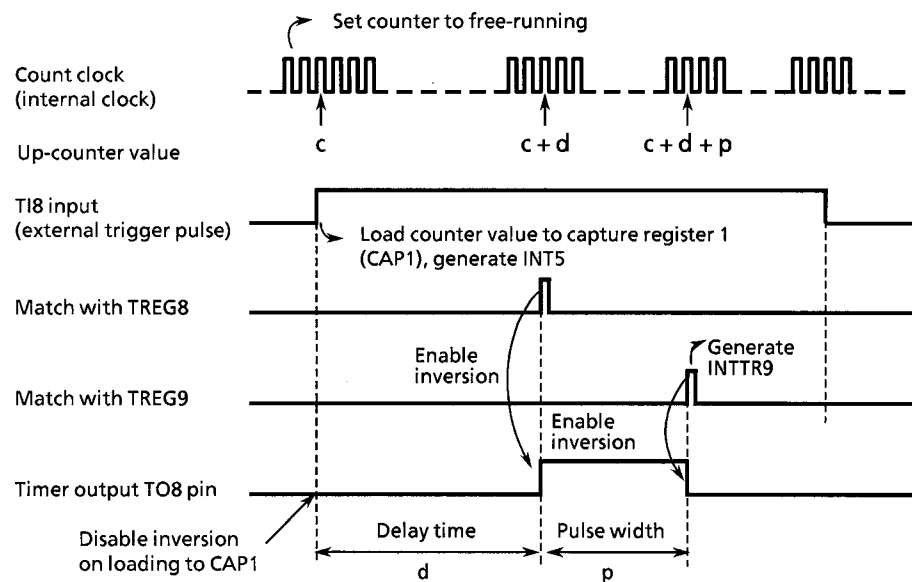

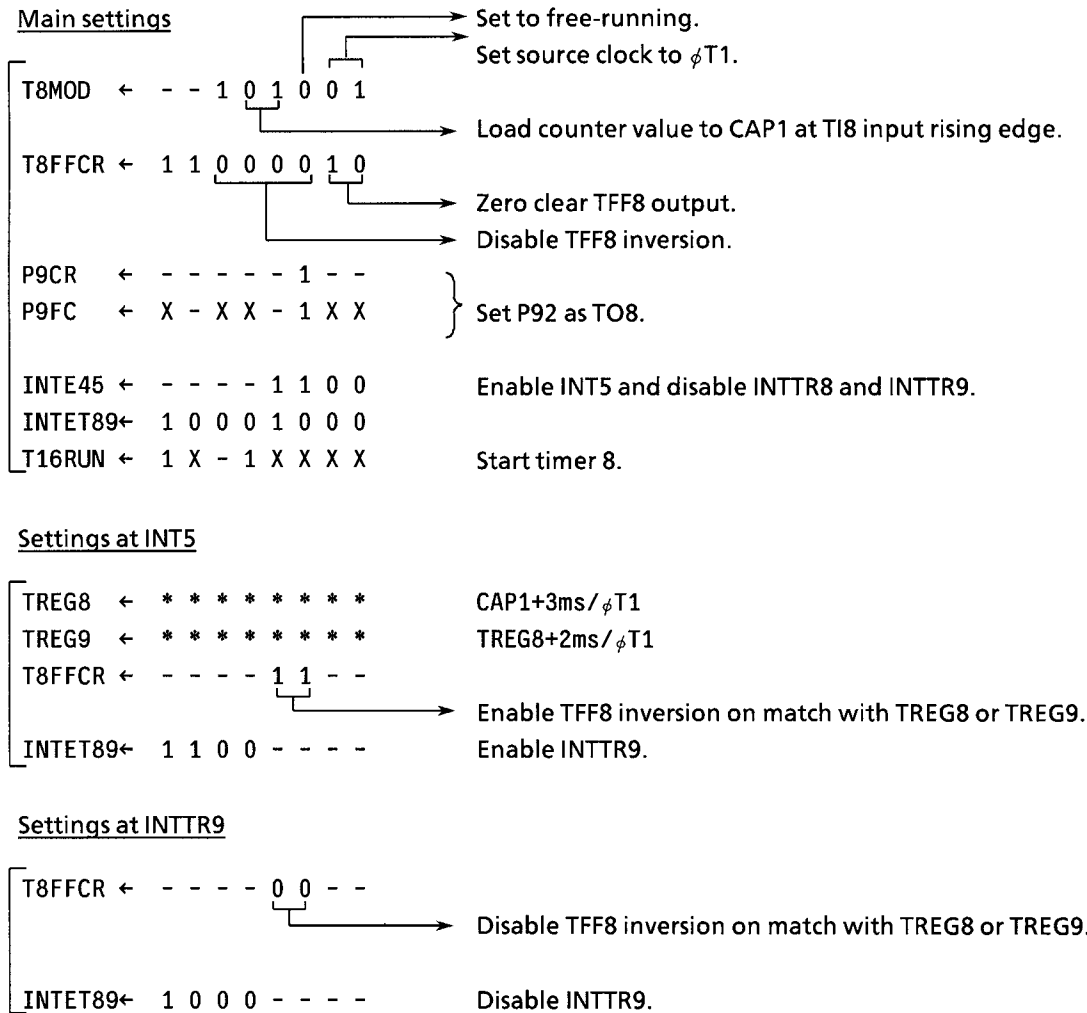

Figure 3.8.6 One-Shot Pulse Output from External Trigger Pulse (With Delay)

Example: On pin TI8, output 2ms one-shot pulse with 3ms-delay after external trigger pulse.

Note: X : Don't care - : No change

If delay time is not required, invert timer flip-flop TFF8 by loading capture register 1 (CAP1). Set timer register TREG9 to the sum of the one-shot pulse width (p) and the value of CAP1 at interrupt INT5 (c) (c + p). Set the TFF8 inversion on a match between TREG9 and UC8, and select inversion enable. On interrupt INTTR9, disable the TFF8 inversion.

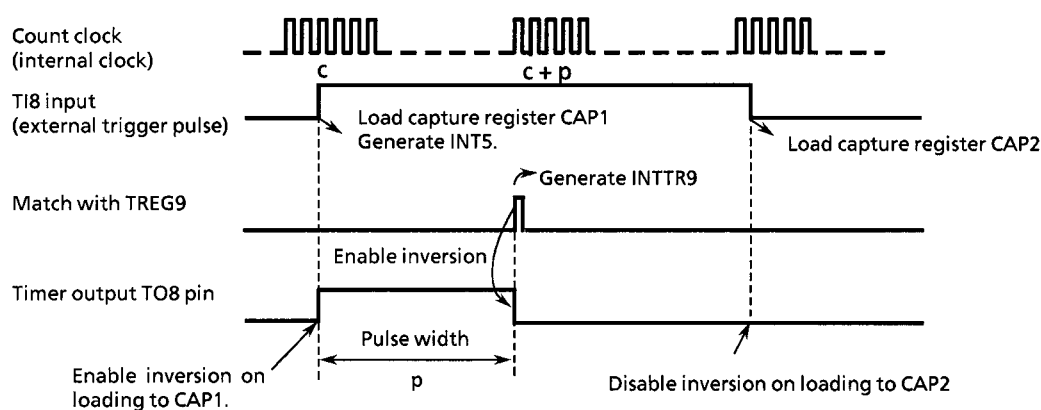

Figure 3.8.7 External Trigger Pulse One-Shot Pulse Output (No Delay)

[2] Frequency measurement

The frequency of an external clock can be measured by the capture function.

The frequency is measured by combining the 8-bit timers (timers 0, 1) in 16-bit event counter mode. (Timers 0 and 1 are used to set the measuring time by inverting TFF1.)

Select the TI8 input as the timer 8 count clock and count timer 8 on the external clock input. Set timer 8 mode control register T8MOD<CAP12M1, 0> to 11. This setting loads the counter value of 16-bit up-counter UC8 into capture register CAP1 on the rising edge of timer flip-flop TFF1. It also loads the counter value into capture register CAP2 on the falling edge of timer flip-flop TFF1. TFF1 is the timer flip-flop of the 8-bit timers (timers 0, 1).

Based on the measuring time, the frequency is calculated from the difference between capture registers CAP1 and CAP2 at the 8-bit timer interrupts (INTT0 or INTT1).

Figure 3.8.8 Frequency Measurement

For example, if TFF1 (8-bit timer flip-flop) is set to 1 for 0.5s, and the difference between CAP1 and CAP2 is 100, the frequency is $100 \div 0.5 \text{ s} = 200 \text{ Hz}$.

[3] Pulse width measurement

The high-level width of an external pulse can be measured using the 16-bit timer capture function.

To measure the pulse width, first set 16-bit up-counter UC8 to operate as a free-running up-counter driven by an internal clock. Using the capture function, load the up-counter value into capture registers CAP1 and CAP2 on the rising and falling edges respectively of the external pulse being measured on the TI8 pin.

Using these settings, the high-level pulse width can be calculated during INT5 interrupt processing by multiplying the difference between CAP1 and CAP2 by the internal clock cycle.

For example, if the difference between CAP1 and CAP2 is 100 and the internal clock cycle is 0.8 μ s, the pulse width is $100 \times 0.8 \mu\text{s} = 80 \mu\text{s}$.

Caution is required when the width of the pulse being measured exceeds the maximum UC8 count time (which is determined by the clock source). Software processing is required in this case.

Figure 3.8.9 Pulse Width Measurement

Note: Measure pulse width by setting the timer 8 mode control register T8MOD<CAP12M1, 0> to 10. External interrupt INT5 is generated on the falling edge of the TI8 input pin. At other settings, INT5 is generated on the rising edge of TI8.

It is also possible to measure the width of low level external pulses. In this case, the pulse width is calculated during the interrupt processing for the second INT5 interrupt by multiplying the internal clock cycle by the difference between the value of C2 at the first INT5 interrupt and the value of C1 at the second INT5 interrupt. However, as the first C2 value has been overwritten by the time of the second INT5 interrupt, the C2 value must be saved during processing of the first INT5 interrupt.

[4] Time difference measurement

The time difference between two events can be measured using the 16-bit timer capture function.

To measure time difference, first set the 16-bit up-counter UC8 to operate as a free-running up-counter driven by an internal clock. Load the value of up-counter UC8 into capture register CAP1 on a rising edge detected on the TI8 pin input pulse. Interrupt INT5 is generated at this time.

Similarly, on a rising edge detected on the TI9 pin input pulse, load the up-counter UC8 value into capture register CAP2. Interrupt INT6 is generated at this time.

When both values have been loaded into the capture registers, calculate the time difference by multiplying the difference between CAP2 and CAP1 by the internal clock cycle.

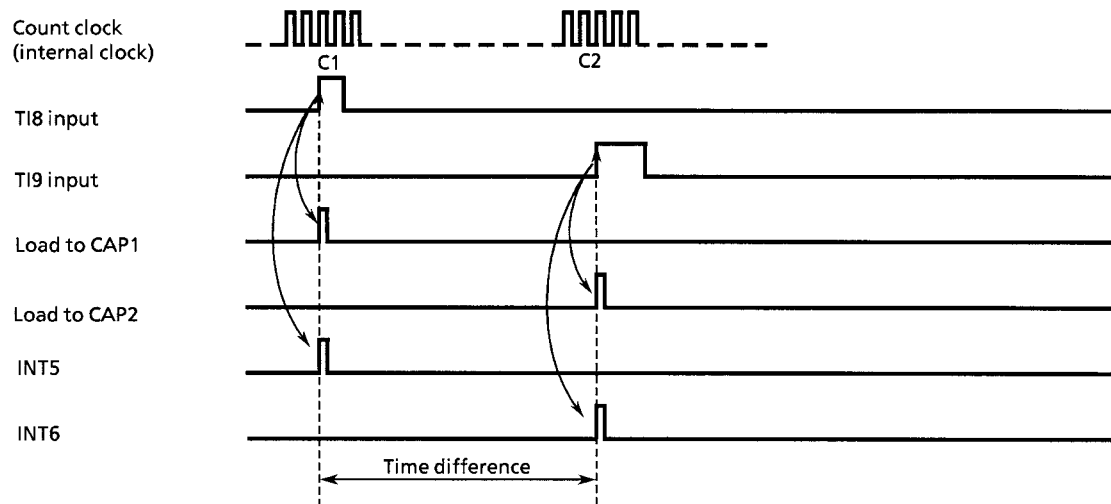

Figure 3.8.10 Time Difference Measurement

(5) Phase output (only available on timer 8)

Signals with a user-specified phase difference can be output using the 16-bit timer.

Select an internal clock as the clock source and set the 16-bit up-counter UC8 to free-running. Set the phase difference in 16-bit timer registers TREG8 and TREG9, set timer flip-flops TFF8 and TFF9 to invert when a match is detected for TREG8 and TREG9, and output the flip-flop values from TO8 and TO9.

Figure 3.8.11 Phase Output

Table 3.8.1 lists the cycles (counter overflow times) that can be set for each clock source.

Table 3.8.1 16-Bit Up-Counter Overflow Times

	24 MHz	
ϕ T1	21.85	ms
ϕ T4	87.38	ms
ϕ T16	349.53	ms

3.9 Serial Channels

The TMP95CU54A has two internal serial input/output channels. The serial channels have the following four operating modes.

- I/O interface mode
 - Mode 0: Can be used to expand the I/O by sending and receiving I/O data and the associated synchronizing signal (SCLK).
- Universal asynchronous receiver transmitter (UART) mode
 - Mode 1: Send/receive data length: 7 bits
 - Mode 2: Send/receive data length: 8 bits
 - Mode 3: Send/receive data length: 9 bits

A parity bit can be added in modes 1 and 2. Mode 3 has a wake-up function that allows a master controller to activate slave controllers via a serial link (multi-controller system).

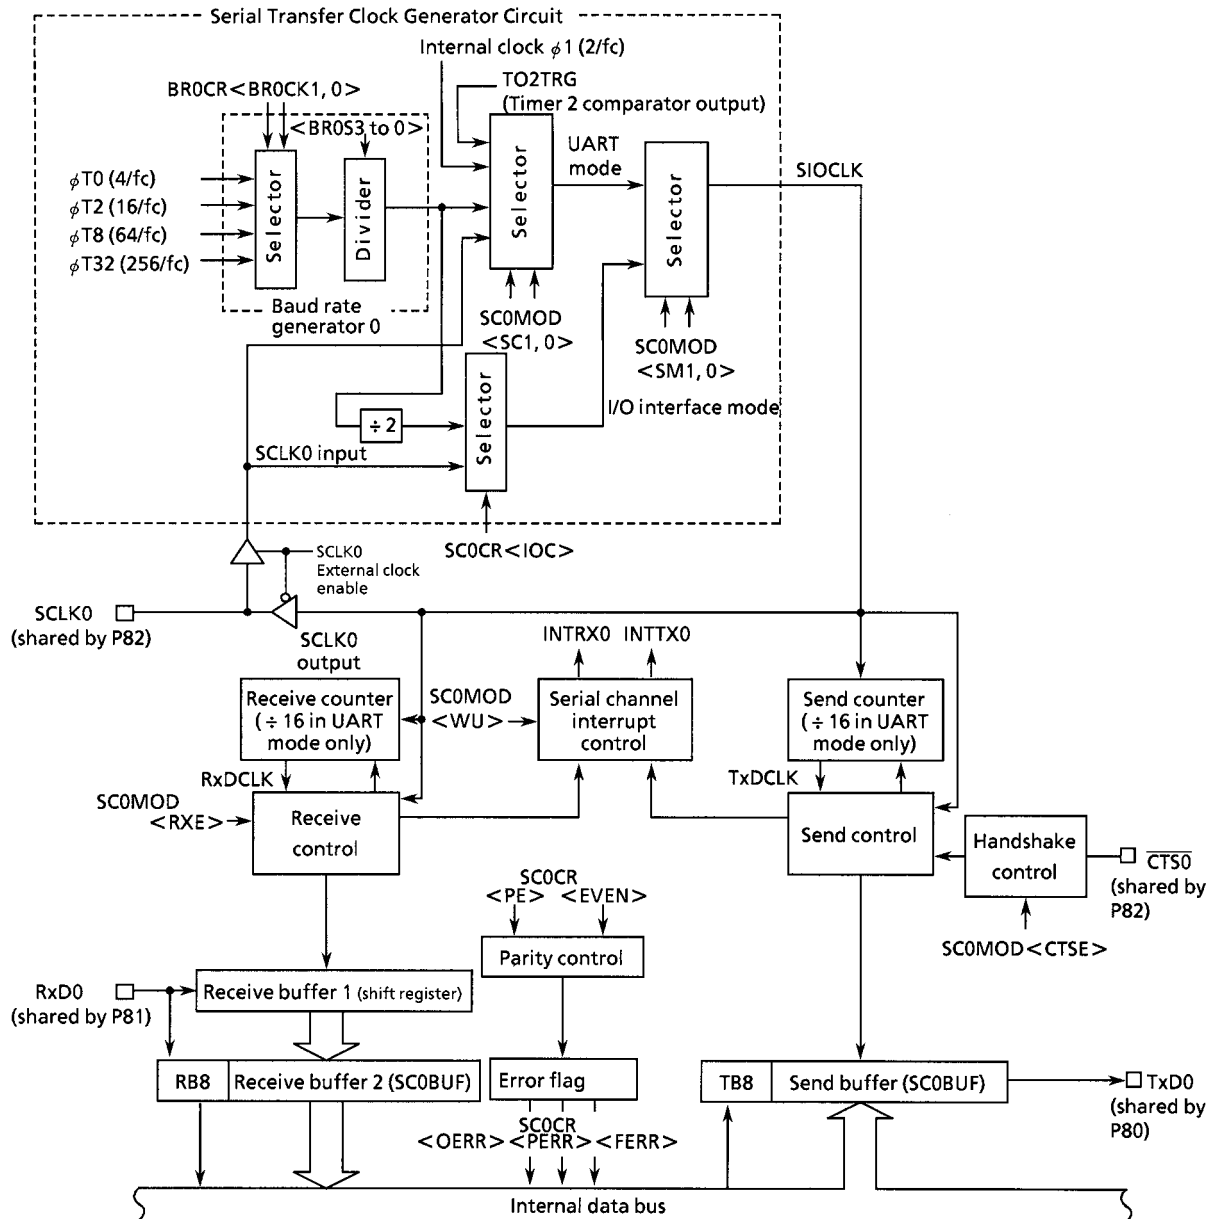

Figure 3.9.1 Block Diagram of Serial Channel 0

3.9.1 Serial Channel Registers

Each serial channel is controlled by three control registers (SC0CR, SC0MOD, and BR0CR in the case of channel 0). Data sent and received are stored in the serial send/receive buffer register in each channel (SC0BUF in the case of channel 0).

(1) Serial channel 0

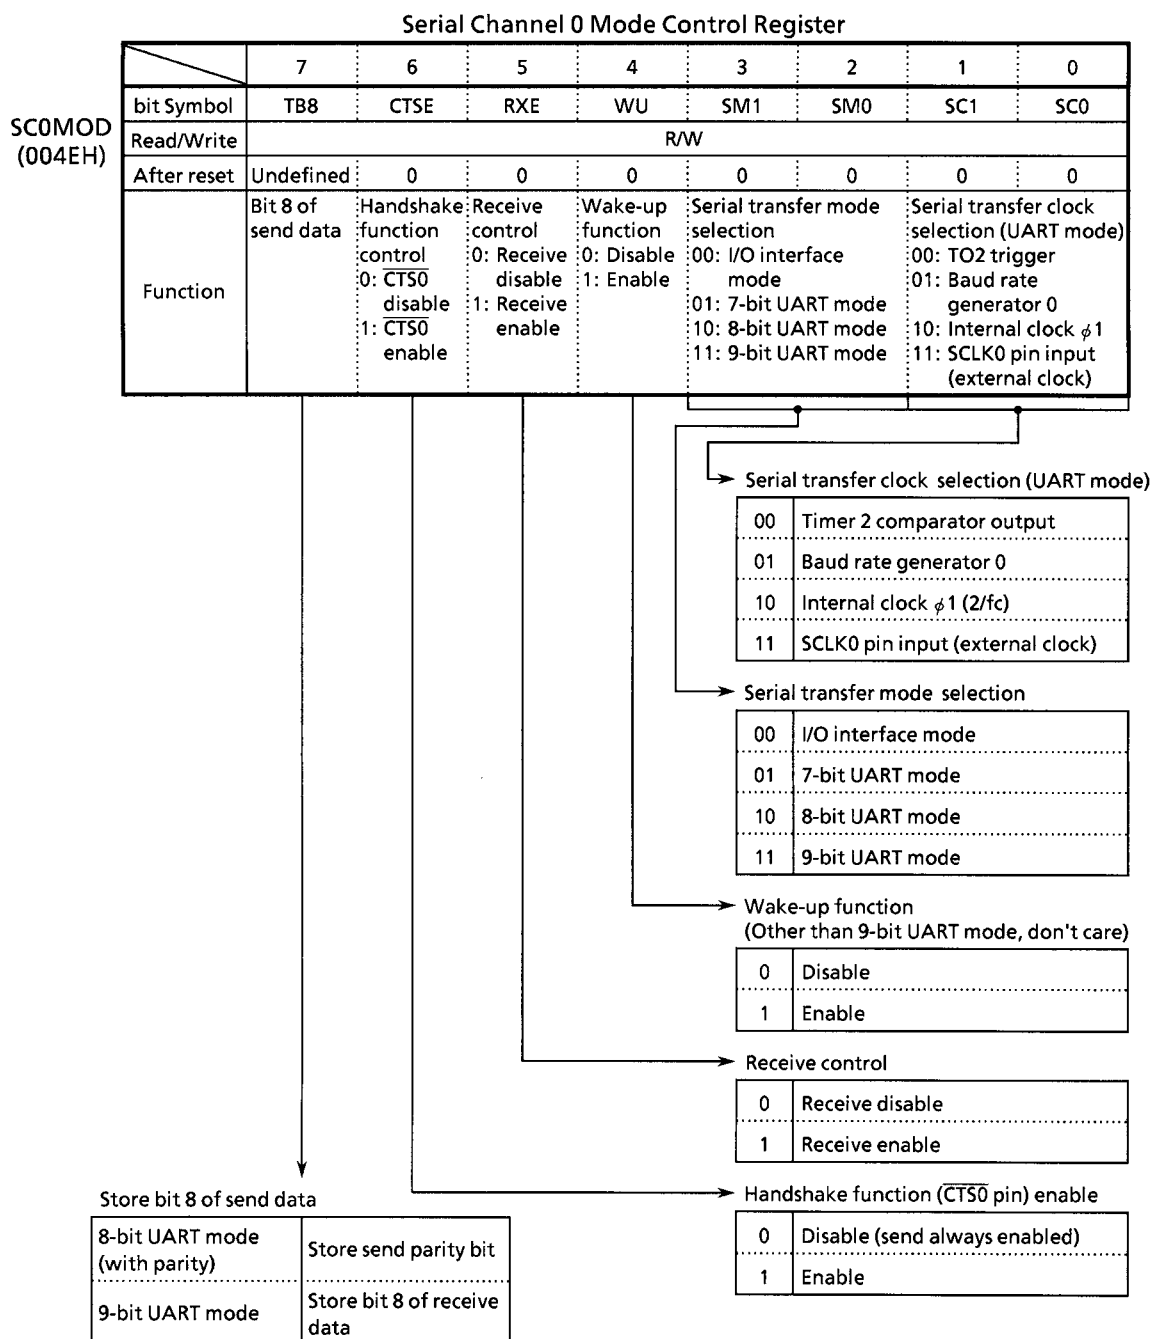

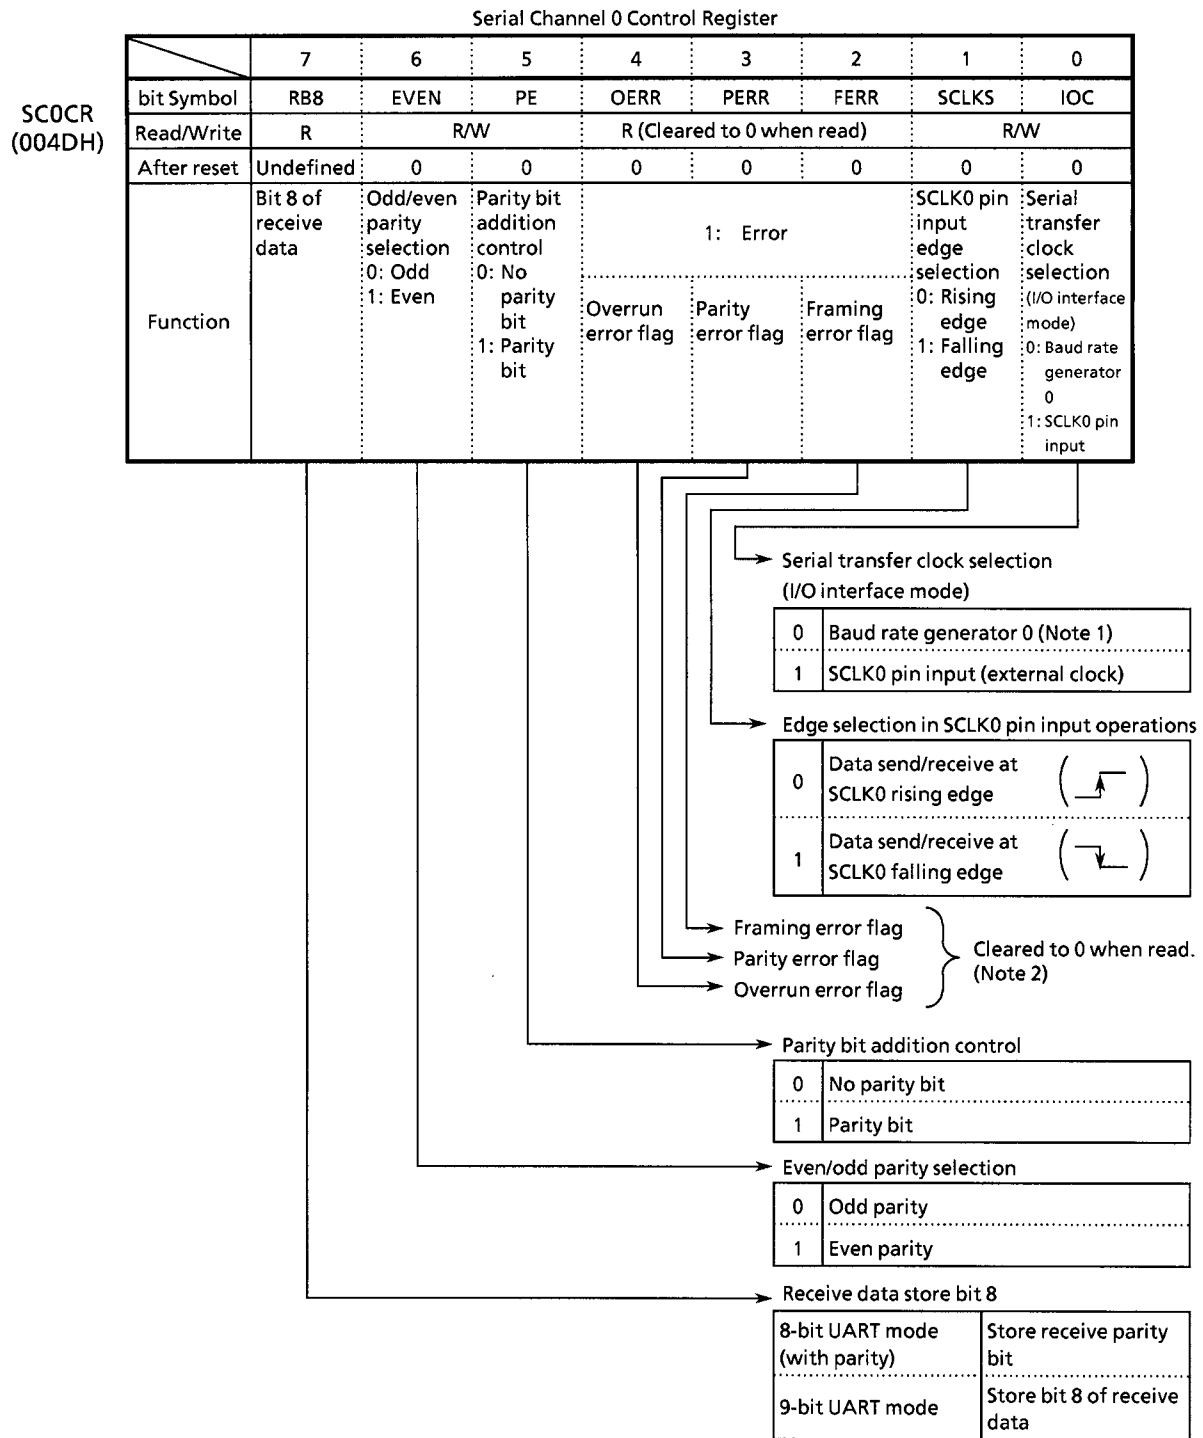

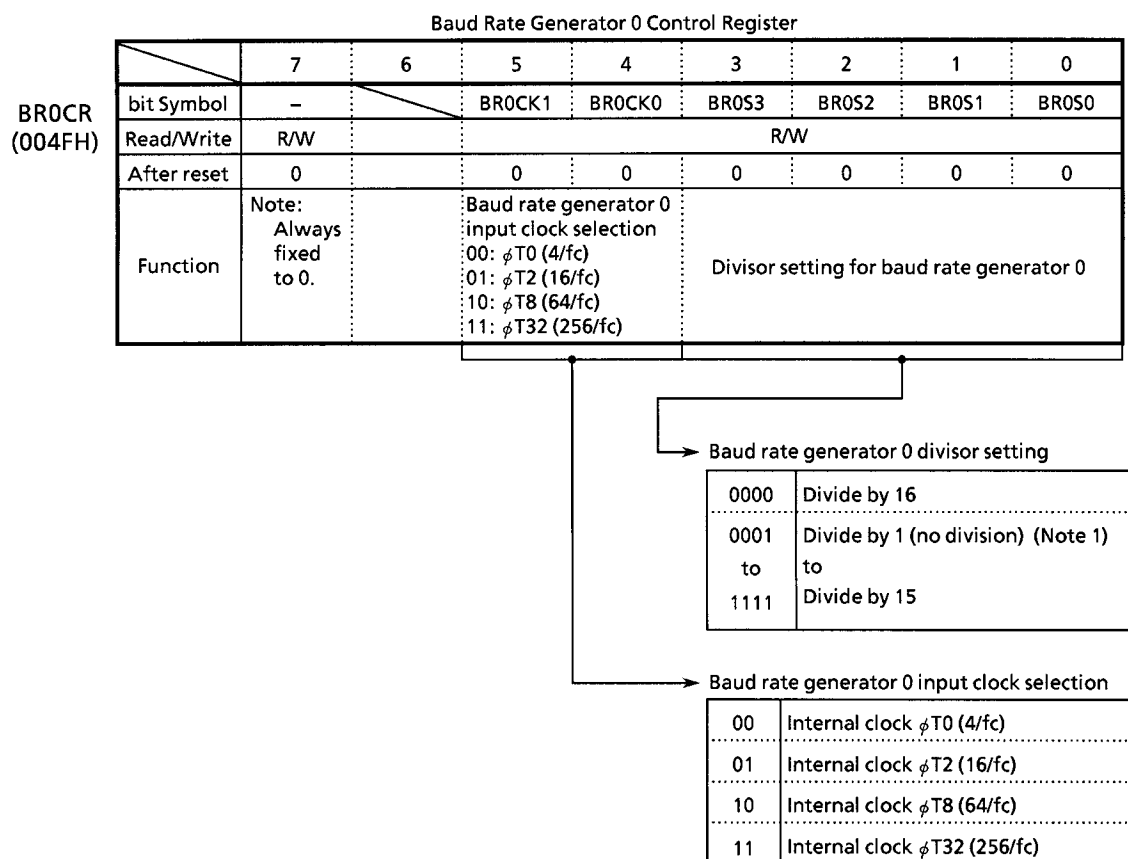

Figure 3.9.2 Serial Channel Related Register (1/6)

Note 1: To use the baud rate generator, set T16RUN<PRRUN> to 1 and run the prescaler.

Note 2: As the error flags are all cleared to 0 after reading, don't test only one bit with a bit test instruction.

Figure 3.9.2 Serial Channel Related Register (2/6)

Note 1: The baud rate generator can be divided by 1 in UART mode only. Do not use this setting in I/O interface mode.

Note 2: Don't read from or write to BR0CR register during sending or receiving.

Serial Channel 0 Buffer Register

SC1BUF (0050H)
Read-modify-write instructions prohibited.

Figure 3.9.2 Serial Channel Related Registers (6/6)

3.9.2 Block Structure

As serial channels 0 and 1 operate identically, the following uses channel 0 as an example.

(1) Serial transfer clock generator circuit

The serial transfer clock generator circuit generates SIOCLK (internal signal), which is the send/receive basic clock. To generate SIOCLK, select the clock source required for the generation.

[1] I/O interface mode

As the clock source, select either baud rate generator 0, or SCLK0 from an external source. Set the clock source in bit 0 (<IOC>) of serial channel 0 control register SC0CR.

When baud rate generator 0 is selected (<IOC> = 0), this circuit generates SIOCLK by dividing the output of the baud rate generator by 2.

When external SCLK0 is selected (<IOC> = 1), SIOCLK is set to the same value as the external source.

[2] UART mode

In addition to the clock sources in I/O interface mode, the comparator output of timer 2 and the internal clock $\phi 1$ (2/fc) can also be selected as clock sources.

Bits 1 and 0 of serial channel 0 mode control register SC0MOD<SC1, 0> select the clock source. SIOCLK is set to the same value as the selected clock source.

(2) Receive counter

The receive counter is a 4-bit binary counter used in UART mode.

The receive counter uses SIOCLK as the count clock to generate receive sampling clock RxDCLK(internal signal).

(3) Receive control

[1] I/O Interface mode

In I/O interface mode, the receive data input to the RxD0 pin are sampled synchronously with transfer clock SCLK0.

Setting serial channel 0 control register SC0CR<IOC> to 0 samples the received data on the rising edge of SCLK0. Setting SC0CR<IOC> to 1 samples the data on the rising or the falling edge of SCLK0 as determined by the setting of SC0CR<SCLKS>.

[2] UART mode

The receive data are sampled bit by bit using RxDCLK, which is generated by the receive counter. Each bit of data is sampled three times, using majority rule. If two or more instances of the same value are detected among three samples, the circuit recognizes the data as receive data. If the sampled data are 1, 0, 1, for example, the data are evaluated as 1; if 0, 0, 1, the data are evaluated as 0.

(4) Receive buffer

The receive buffer has a double-buffer configuration to prevent overrun error. Receive buffer 1 stores the data received bit by bit.

When receive buffer 1 contains seven or eight bits of data, the data are transferred to receive buffer 2 (SC0BUF), generating interrupt INTRX0.

Reading the data in receive buffer 2 clears the interrupt request flag INTRX0<IRX0C>.

Even before the CPU reads the data in receive buffer 2, the next data can be received and stored in receive buffer 1.

However, receive buffer 2 must be read before all bits of the next data frame are received by buffer 1. If not, an overrun error occurs and the contents of receive buffer 1 are lost, although the contents of receive buffer 2 and the serial channel 0 control register SC0CR<RB8> are preserved.

In 8-bit UART mode (mode 2) with parity added, the parity bit is stored in SC0CR<RB8>. In 9-bit UART mode (mode 3), the MSB is stored in SC0CR<RB8>.

(5) Send counter

The send counter is a 4-bit binary counter used in UART mode.

The send counter uses SIOCLK as its count clock, generating send clock TxDCLK (internal signals).

Figure 3.9.3 Send Clock Generation

(6) Send control

[1] I/O interface mode

In I/O interface mode, the TMP95CU54A outputs send data from the TxD0 pin synchronously with transfer clock SCLK0.

Setting serial channel 0 control register SC0CR<IOC> to 0 outputs send data on the rising edge of transfer clock SCLK0.

Setting SC0CR<IOC> to 1 outputs the send data on the rising or falling edge of SCLK0 as determined by the setting of SC0CR<SCLKS>.

[2] UART mode

In UART mode, the send data are output synchronously with the rising edge of the TxDCLK send clock generated by the send counter.

(7) Send buffer

Send buffer (SC0BUF) outputs the send data written by the CPU, beginning with the least significant bit.

When all bits are output, the empty send buffer generates interrupt request INTTX0.

(8) Parity control

Parity bit addition can only be set in 7-bit UART mode (mode 1) and 8-bit UART mode (mode 2).

When serial channel 0 control register SC0CR<PE> is set to 1, data can be sent with a parity bit added. SC0CR<EVEN> selects even parity or odd parity.

A send operation automatically generates the parity bit determined by the send data. In mode 1, SC0BUF<TB7> stores the parity bit; in mode 2, serial channel 0 mode control register SC0MOD<TB8> stores the parity bit.

Set both <PE> and <EVEN> before writing the send data in SC0BUF.

When receiving, parity is calculated from the received data and compared with the received parity bit. If the parities differ, a parity error occurs and parity error flag SC0CR<PERR> is set to 1.

(9) Error flags

To improve the reliability of data reception, serial channel 0 control register SC0CR contains the following three error flags.

[1] Overrun error <OERR>

When all bits of the next data frame have been received in receive buffer 1 while valid data are stored in receive buffer 2 (SC0BUF), an overrun error occurs.

At an overrun error, the data received in buffer 1 are lost.

[2] Parity error <PERR>

The parity bit determined by the data stored in receive buffer 2 (SC0BUF) is compared with the received parity bit. If the parities differ, a parity error occurs.

[3] Framing error <FERR>

The stop bit of data received is sampled three times. If the majority of samples are 0, a framing error occurs.

If an error occurs, these error flags are set to 1. Reading the SC0CR register clears the error flags to 0. If an error occurs, fix by software.

(10) Handshake function control (only supported in UART mode)

The serial channels use the $\overline{\text{CTS0}}$ input pin to send data in one-frame units, thus preventing an overrun error. The serial channel 0 mode control register $\text{SC0MOD}<\text{CTSE}>$ enables or disables the handshake function.

In send operations, sending starts when a low level signal is input to the $\overline{\text{CTS0}}$ pin.

When $\overline{\text{CTS0}}$ goes high, data sending is halted when sending of the current data completes and the pin is set to wait state. Sending is not restarted until $\overline{\text{CTS0}}$ goes low again.

Although an $\overline{\text{RTS0}}$ pin is not provided, any port can be assigned to the $\overline{\text{RTS0}}$ function. When the receiving side has completed reception, the receiving interrupt processing routine outputs a high-level signal from the port assigned to the $\overline{\text{RTS0}}$ function. A handshake function can be easily configured by connecting the sending side $\overline{\text{CTS0}}$ pin and the receiving side $\overline{\text{RTS0}}$ pin.

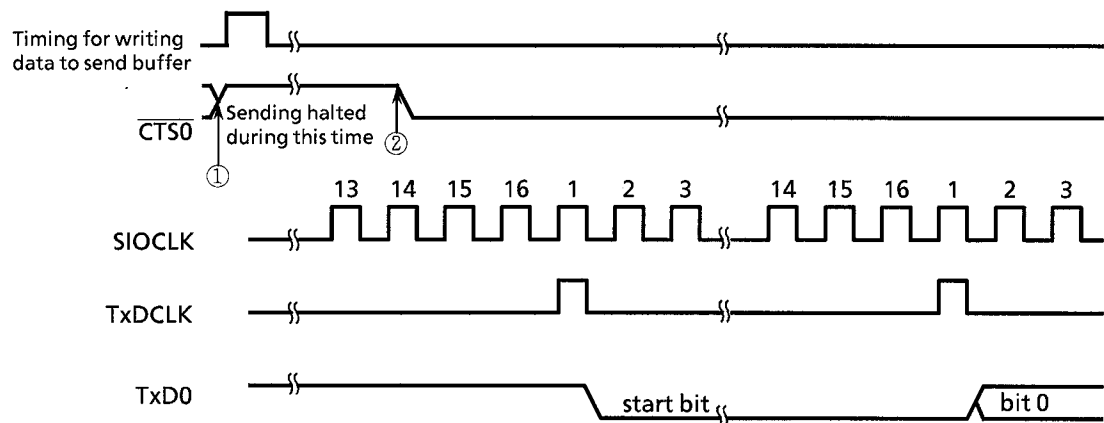

Figure 3.9.4 Handshake Function

- [1] When the $\overline{\text{CTS0}}$ signal rises during sending, sending of the current data frame is completed, and sending of the next data frame halts.
- [2] Sending begins at the first TxDCLK clock falling edge after the $\overline{\text{CTS0}}$ signal drops.

Figure 3.9.5 $\overline{\text{CTS0}}$ (Clear to Send) Signal Timing

3.9.3 Description of Operation

As serial channels 0 and 1 operate identically, the following uses channel 0 as an example.

(1) Setting send/receive clock transfer rate

[1] Transfer rate setting with baud rate generator selected

The baud rate generator is a circuit used to generate a clock source for the send/receive clock that controls the serial channel transfer rate.

The input clock for generating the clock source can be selected from among $\phi T0$ ($4/f_c$), $\phi T2$ ($16/f_c$), $\phi T8$ ($64/f_c$), or $\phi T32$ ($256/f_c$) from the 9-bit prescaler (see 3.7.2 (1), Prescaler). The 8-bit and 16-bit timers share the prescaler. Bits 5, 4 of baud rate generator control register BR0CR<BR0CK1:0> select the input clock.

The selected input clock is divided by the 4-bit divider performing 1 to 16 divisions. Bits 3 to 0 of BR0CR<BR0S3:0> set the divider. The divided clock is the output clock for the baud rate generator.

The following are the transfer rate calculation formulas when the baud rate generator is selected:

- I/O interface mode

$$\text{Transfer rate [bps]} = \frac{\text{Baud rate generator input clock [Hz]}}{\text{Baud rate generator divisor (2 to 16)}} \div 2$$

Note: In I/O interface mode, do not set divisor to 1.

- UART mode

$$\text{Transfer rate [bps]} = \frac{\text{Baud rate generator input clock [Hz]}}{\text{Baud rate generator divisor (1 to 16)}} \div 16$$

The relationship between the input clock and the source clock (f_c) is:

$$\phi T0 = 4/f_c$$

$$\phi T2 = 16/f_c$$

$$\phi T8 = 64/f_c$$

$$\phi T32 = 256/f_c$$

Accordingly, with the source clock set to 12.288MHz, when $\phi T2$ ($16/f_c$) is selected as the input clock and the divisor is 5, the transfer rate in UART mode is:

$$\text{Transfer rate} = \frac{f_c/16}{5} \div 16 = 12.288 \times 10^6 \div 16 \div 5 \div 16 = 9600[\text{bps}]$$

Table 3.9.1 shows examples of transfer rate settings in UART mode.

- [2] Transfer rate settings with the timer 2 comparator output selected (UART mode only)

The following are the transfer rate calculation formulas when the timer 2 comparator output is selected:

$$\text{Transfer rate [bps]} = \frac{\text{Timer 2 input clock [Hz]}}{\text{TREG2 (1 to 256)}} \div 16$$

The relationship between the timer 2 input clock and the source clock (fc) is:

$$\phi T1 = 8/fc$$

$$\phi T4 = 32/fc$$

$$\phi T16 = 128/fc$$

Accordingly, with the source clock set to 25MHz, when the timer 2 input clock is set to $\phi T1$ and TREG2 is set to 1, the transfer rate is:

$$\text{Transfer rate} = \frac{fc/8}{\text{TREG2}} \div 16 = 24 \times 10^6 \div 8 \div 1 \div 16 = 187500 \text{ [bps]}$$

Table 3.9.2 shows examples of the transfer rate settings.

- [3] Transfer rate settings with external SCLK input selected

The following are the transfer rate calculation formulas when the external SCLK input is selected:

- I/O interface mode

$$\text{Transfer rate [bps]} = \text{external SCLK input [Hz]} \div 2$$

- UART mode

$$\text{Transfer rate [bps]} = \text{external SCLK input [Hz]} \div 16$$

Table 3.9.1 UART Mode Transfer Rate Setting Example (1) (Using Baud Rate Generator)

Unit: Kbps

fc [MHz]	Input clock Divisor	$\phi T0$ (4/fc)	$\phi T2$ (16/fc)	$\phi T8$ (64/fc)	$\phi T32$ (256/fc)
9.830400	1	153.600	38.400	9.600	2.400
	2	76.800	19.200	4.800	1.200
	4	38.400	9.600	2.400	0.600
	8	19.200	4.800	1.200	0.300
	16	9.600	2.400	0.600	0.150
12.288000	5	38.400	9.600	2.400	0.600
	10	19.200	4.800	1.200	0.300
14.745600	1	230.400	57.600	14.400	3.600
	3	76.800	19.200	4.800	1.200
	6	38.400	9.600	2.400	0.600
	12	19.200	4.800	1.200	0.300
17.2032	7	38.400	9.600	2.400	0.600
	14	19.200	4.800	1.200	0.300
19.6608	2	153.600	38.400	9.600	2.400
	4	76.800	19.200	4.800	1.200
	8	38.400	9.600	2.400	0.600
	16	19.200	4.800	1.200	0.300
22.1184	9	38.400	9.600	2.400	0.600

Note: In I/O interface mode, the transfer rates are 8 times the values in this table.

In I/O interface mode, do not set the baud rate generator divisor to 1.

Table 3.9.2 UART Mode Transfer Rate Setting Example (2) (Using Timer 2 Input Clock $\phi T1$)

Unit: kbps

TREG2 \ fc	12.288MHz	12MHz	9.8304MHz	8MHz	6.144MHz
1H	96		76.8	62.5	48

10H	6		4.8		3
14H	4.8				2.4

(2) Data format

Figure 3.9.6 shows the data format for each mode.

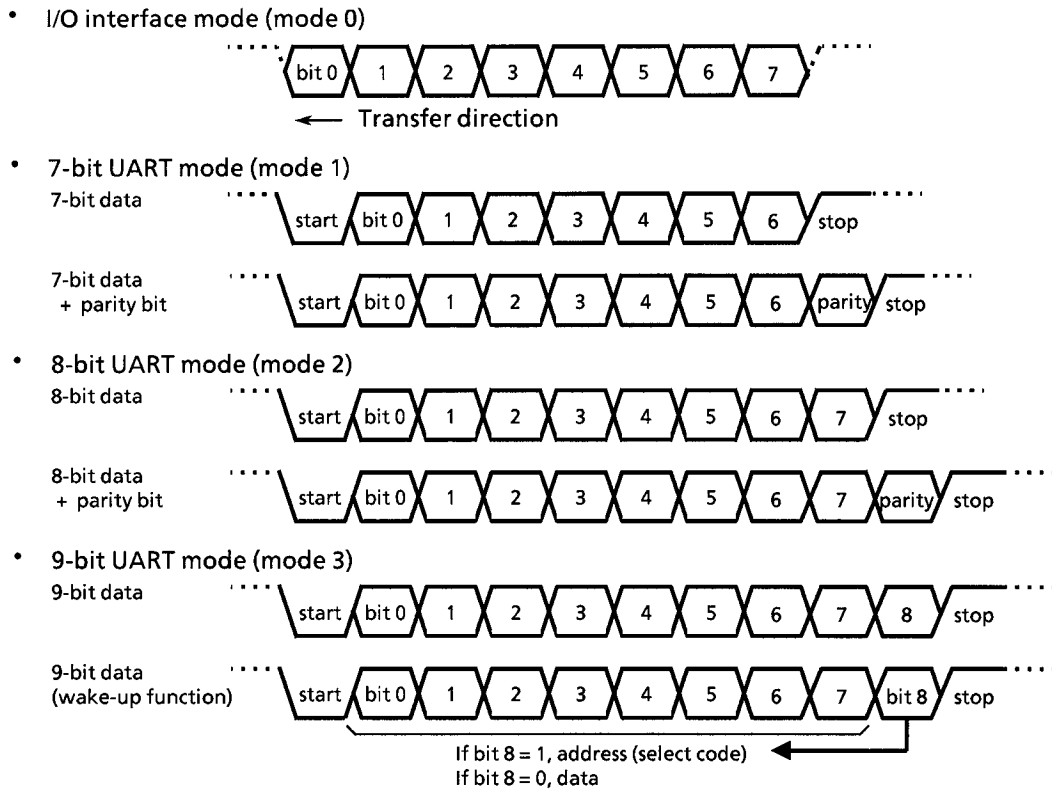

Figure 3.9.6 Data Formats

(3) I/O interface mode (Mode 0)

In this mode, data transfer to an external device is synchronous with the transfer clock.

This mode is used to increase the number of I/O pins for sending or receiving data to an external shift register or other external destinations.

This mode consists of SCLK0 output mode, which outputs a synchronous clock (SCLK0), and SCLK0 input mode, which inputs a synchronous clock (SCLK0) from an external source.

Figures 3.9.7 and 3.9.8 show connection examples of SCLK0 output and input modes.

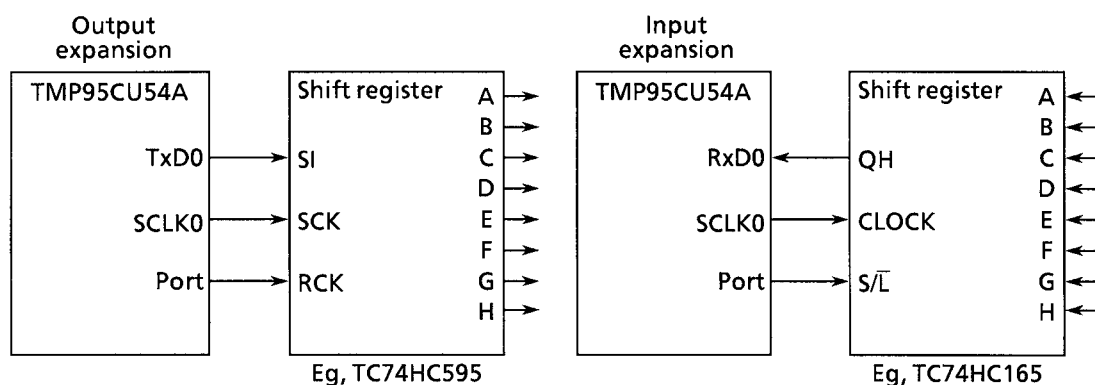

Figure 3.9.7 Example of SCLK0 Output Mode Connection

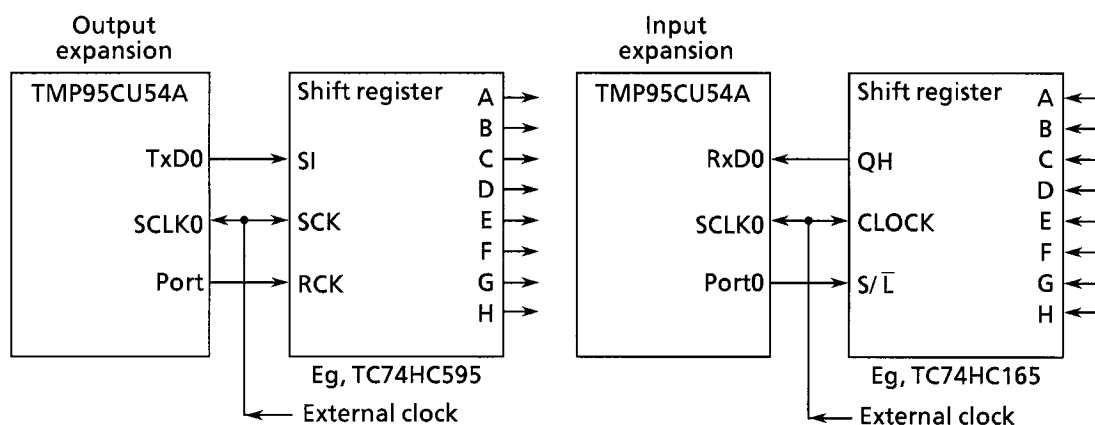

Figure 3.9.8 Example of SCLK0 Input Mode Connection

[1] Sending

In SCLK0 output mode, each time the CPU writes data in the send buffer, eight data bits are output from the TxD0 pin, and a transfer clock signal is output from the SCLK0 pin. When all data have been sent, INTES0<ITX0C> is set, triggering an INTTX0 interrupt request.

Figure 3.9.9 Sending in I/O Interface Mode (SCLK0 Output Mode)

In SCLK0 input mode, pin TxD0 outputs eight transfer data bits when SCLK0 input is supplied and data are written to the send buffer by the CPU.

When all data have been sent, INTES0<ITX0C> is set, triggering an INTTX0 interrupt request.

Figure 3.9.10 Sending in I/O Interface Mode (SCLK0 Input Mode)

[2] Receiving

In SCLK0 output mode, whenever the receive interrupt flag INTES0<IRX0C> is cleared by the CPU reading the received data, a synchronous clock is output from the SCLK0 pin and the next data frame is shifted to receive buffer 1. When an 8-bit data frame is received, it is transferred to receive buffer 2 (SC0BUF), and INTES0<IRX0C> is set again, triggering an INTRX0 interrupt request.

Figure 3.9.11 Receiving in I/O Interface Mode (SCLK0 Output Mode)

In SCLK0 input mode, if SCLK0 input is supplied when received data are read by the CPU, thus clearing receive interrupt flag INTES0<IRX0C>, the next data frame is shifted into receive buffer 1.

When an 8-bit data frame is received, it is shifted to receive buffer 2 (SC0BUF) and INTES0<IRX0C> is set again, triggering an INTRX0 interrupt request.

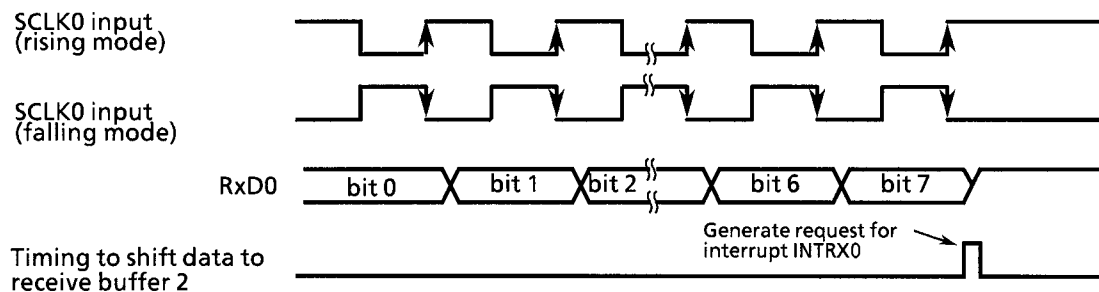

Figure 3.9.12 Receiving in I/O Interface Mode (SCLK0 Input Mode)

Note: To receive data, first enable reception (set SC0MOD<RXE> to 1) for either SCLK0 input mode or output mode.

(4) 7-bit UART mode (Mode 1)

Setting serial channel 0 mode control register SC0MOD<SM1:0> to 01 specifies 7-bit UART mode.

A parity bit may be added in this mode. Enable or disable the addition of a parity bit by serial channel 0 control register SC0CR<PE>.

With <PE> set to 1 (parity bit added), SC0CR<EVEN> selects even or odd parity.

Setting example: send 7-bit data with an even parity bit added:

	7	6	5	4	3	2	1	0	
P8CR	←	-	-	-	-	-	-	1	} Select P80 as TxD0 pin.
P8FC	←	X	-	-	X	-	-	X 1	
SC0MOD	←	X	0	-	X	0	1	0 1	Set 7-bit UART mode.
SC0CR	←	X	1	1	X	X	X	0 0	Add even parity.
BR0CR	←	0	X	1	0	0	1	0 1	Set transfer rate to 2400bps.
T16RUN	←	1	X	-	-	-	-	-	Start prescaler for baud rate generator.
INTES0	←	1	1	0	0	-	-	-	Enable interrupt INTTX0 and set interrupt level to 4.
SC0BUF	←	*	*	*	*	*	*	*	Set send data.

Note: X : Don't care - : No change

(5) 8-bit UART mode (Mode 2)

Setting serial channel 0 mode control register SC0MOD<SM1:0> to 10 selects 8-bit UART mode.

A parity bit may be added in this mode. Enable or disable the addition of a parity bit by serial channel 0 control register SC0CR<PE>. With <PE> set to 1 (parity bit added), SC0CR<EVEN> selects even or odd parity.

Setting example: send 8-bit data with an odd parity bit added:

Main routine settings:

	7	6	5	4	3	2	1	0		
P8CR	←	-	-	-	-	-	0	-	Select P81 (RxD0) as input pin.	
SC0MOD	←	-	0	1	X	1	0	0	1	Set 8-bit UART mode and enable reception.
SC0CR	←	X	0	1	X	X	X	0	0	Add odd parity.
BR0CR	←	0	X	0	1	0	1	0	1	Set transfer rate to 9600bps.
T16RUN	←	1	X	-	-	-	-	-	-	Start the prescaler for baud rate generator.
INTES0	←	-	-	-	-	1	1	0	0	Enable interrupt INTRX0 and set interrupt level 4.

Note: X : Don't care - : No change

Interrupt routine processing example:

Check for errors with SC0CR error flags (<OERR>, <PERR>, <FERR>). If there are no errors, read the data received.

(6) 9-bit UART mode (Mode 3)

Setting the serial channel 0 mode control register SC0MOD<SM1:0> to 11 selects 9-bit UART mode.

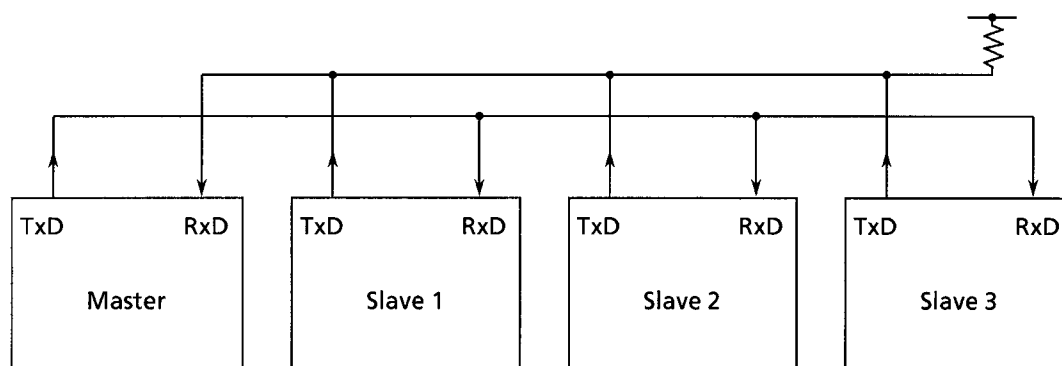

A parity bit cannot be added in this mode.

When sending, the most significant bit (bit 9) is written to SC0MOD<TB8>.

When receiving, the most significant bit is saved in serial channel control register SC0CR<RB8>. When the buffer is written to or read from, the most significant bit is always read or written first.

Wake-Up function

In 9-bit UART mode, select the slave controller wake-up function by setting SC0MOD<WU> to 1. When SC0CR<RB8> = 1, received data are interpreted as select code, and an INTRX0 interrupt request occurs.

Note: The TxD pin of the slave controller must always be set to open-drain output mode using the ODE register.

Figure 3.9.13 Serial Link using Wake-Up function

Protocol

- [1] Set the master controller and all slave controllers to 9-bit UART mode.
- [2] Set the serial channel 0 mode control register SC0MOD<WU> of each slave controller to 1 to enable data reception.
- [3] The master controller sends one frame with the most significant bit (bit 8) SC0MOD<TB8> set to 1. This frame contains the 8-bit select code of a slave controller.

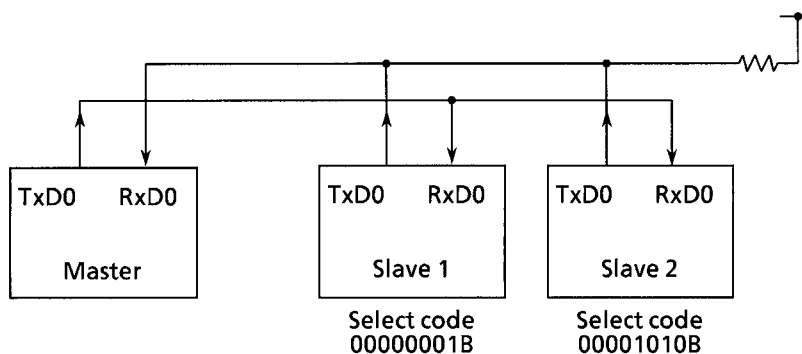

- [4] The slave controllers receive the above data frame. The slave controller whose select code matches the select code in the data frame received clears its SC0MOD<WU> bit to 0.
- [5] The master controller sends data frames with their most significant bit (bit 8) SC0MOD<TB8> set to 0 to the specified slave controller (the controller whose SC0MOD<WU> bit is cleared to 0).

- [6] The slave controllers whose SC0MOD<WU> bit is 1 ignore the received data as interrupt INTRX0 is not generated when the most significant bit (bit 8) SC0CR<RB8> remains cleared to 0 (when data are sent). The slave controller whose SC0MOD<WU> bit is cleared to 0 can inform the master controller of the termination of a send it received by sending data to the master controller.

Setting example: When linking two slave controllers serially with the master controller using internal clock $\phi 1$ as the transfer clock.

As serial channels 0 and 1 operate identically in this mode, the following describes channel 0 only.

- Setting the master controller

Main routine:

P8CR	←	- - - - -	0 1	} Select P80 as Tx/D0 pin, and P81 as Rx/D0 pin.
P8FC	←	X - - X - -	X 1	
INTES0	←	1 1 0 0 1 1 0 1		Enable interrupt INTTX0 and set interrupt level to 4.
				Enable interrupt INTRX0 and set interrupt level to 5.
SC0MOD	←	1 0 1 0 1 1 1 0		Set $\phi 1$ as transfer clock and set 9-bit UART mode.
SC0BUF	←	0 0 0 0 0 0 0 1		Set select code for slave controller 1.

INTTX0 interrupt routine:

SC0MOD	←	0 - - - - -	Set SC0MOD<TB8> to 0.
SC0BUF	←	* * * * *	Set send data.

Note: X : Don't care - : No change

- Setting slave controller 2

Main routine:

P8CR	←	- - - - -	0 1	} Select P80 as Tx/D0 pin (open-drain output), and P81 as Rx/D0 pin.
P8FC	←	X - - X - -	X 1	
ODE	←	X X X - -	- - -	
INTES0	←	1 1 0 1 1 1 1 0		Enable interrupts INTTX0 and INTRX0.
SC0MOD	←	0 0 1 1 1 1 1 0		Set 9-bit UART mode using transfer clock $\phi 1$ (2/fc), and enable wake-up mode (set <WU> to 1).

INTRX0 interrupt routine:

Compare SC0BUF and select code (00001010B). If these match, clear SC0MOD<WU> to 0.

Note: X : Don't care - : No change

(7) Signal generation timing

[1] In I/O Interface mode

Timing for send interrupt generation	SCLK0 output mode	Immediately after rise of last SCLK0 signal (See Figure 3.9.9)
	SCLK0 input mode	Immediately after rise (rising mode) or fall (falling mode) of last SCLK0 signal (See Figure 3.9.10)
Timing for receive interrupt generation	SCLK0 output mode	Immediately after final SCLK0 (When received data are transferred to receive buffer 2 (SC0BUF)) (See Figure 3.9.11)
	SCLK0 input mode	Immediately after final SCLK0 (When received data are transferred to receive buffer 2 (SC0BUF)) (See Figure 3.9.12)

[2] In UART mode

Receive

Mode	9-Bit	8-Bit + Parity	8-Bit, 7-Bit + Parity, 7-Bit
Timing for interrupt generation	Around center of bit 8	Around center of parity bit	Around center of stop bit

3.10 Analog/Digital Converter

The TMP95CU54A incorporates a high-speed, high-precision 10-bit successive approximation type analog/digital converter (AD converter) with 8-channel analog input.

Figure 3.10.1 is a block diagram of the AD converter. The 8-channel analog input pins (AN0 to AN7) are shared by input-only port A and can thus be used as an input port.

Note: When the power is reduced by setting IDLE2, IDLE1, or STOP mode, with some timings, the system may enter standby mode even though the internal comparator is still enabled. Therefore, be sure to check that AD converter operations are halted before executing a HALT instruction.

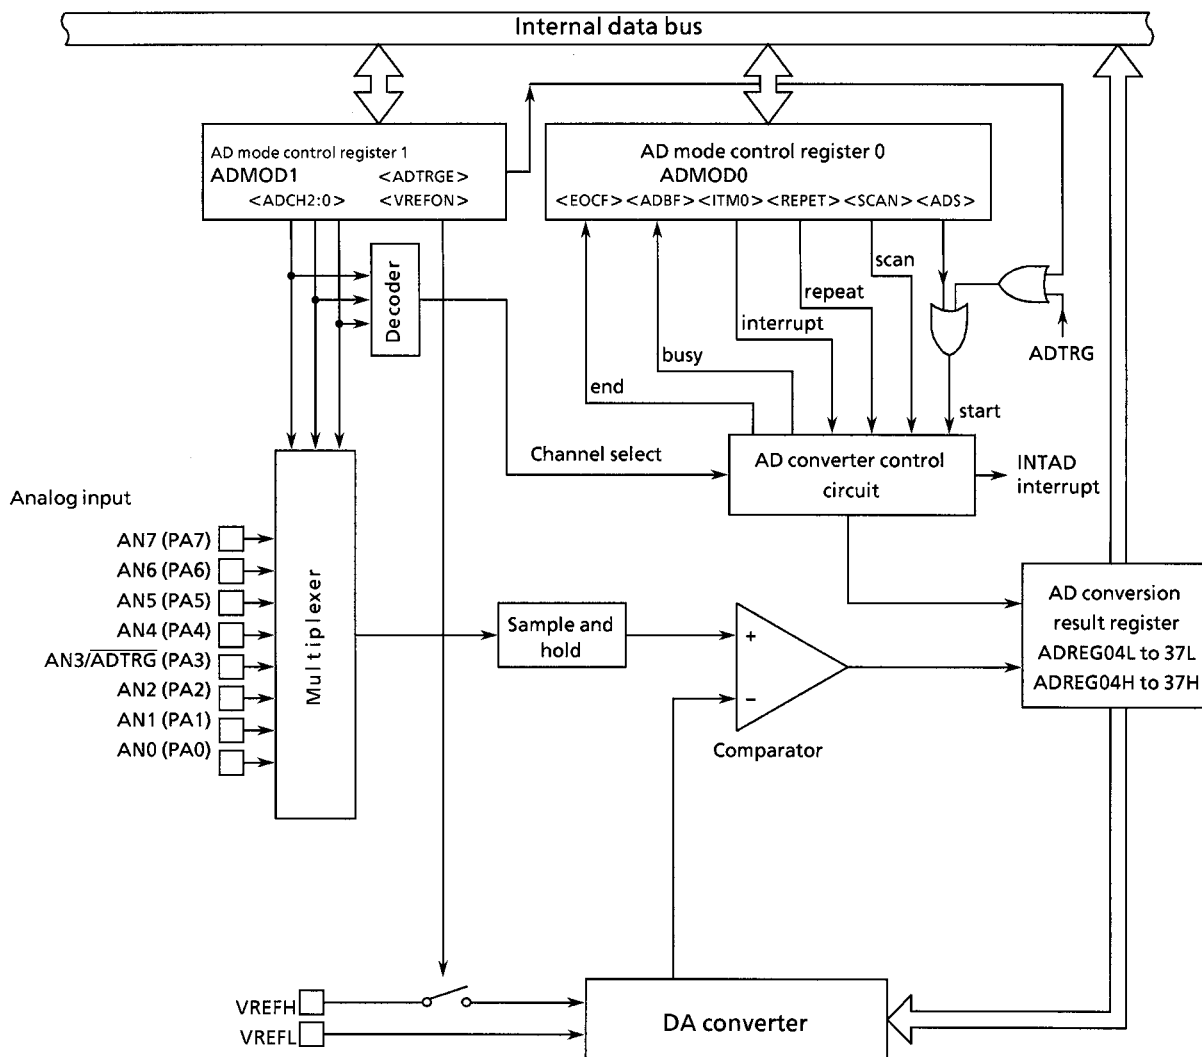

Figure 3.10.1 AD Converter Block Diagram

3.10.1 Analog/Digital Converter Registers

The AD converter is controlled by two AD mode control registers: ADMOD0 and ADMOD1. Eight AD conversion data upper and lower registers (ADREG04H/L, ADREG15H/L, ADREG26H/L, and ADREG37H/L) store the AD conversion results.

Figures 3.10.2 (1-4) show registers related to the AD converter.

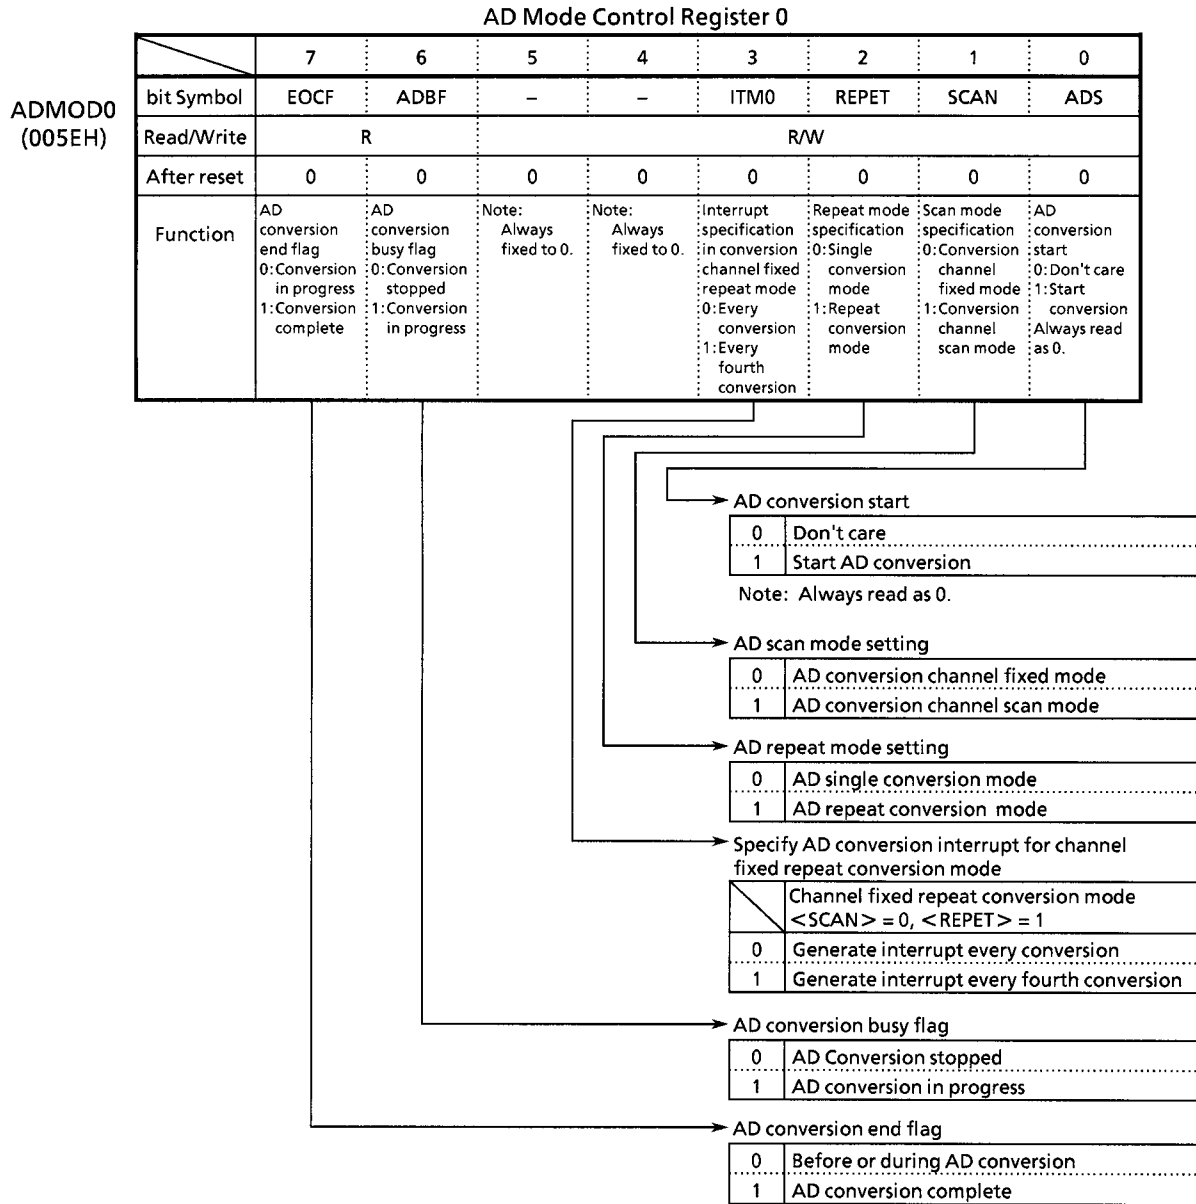

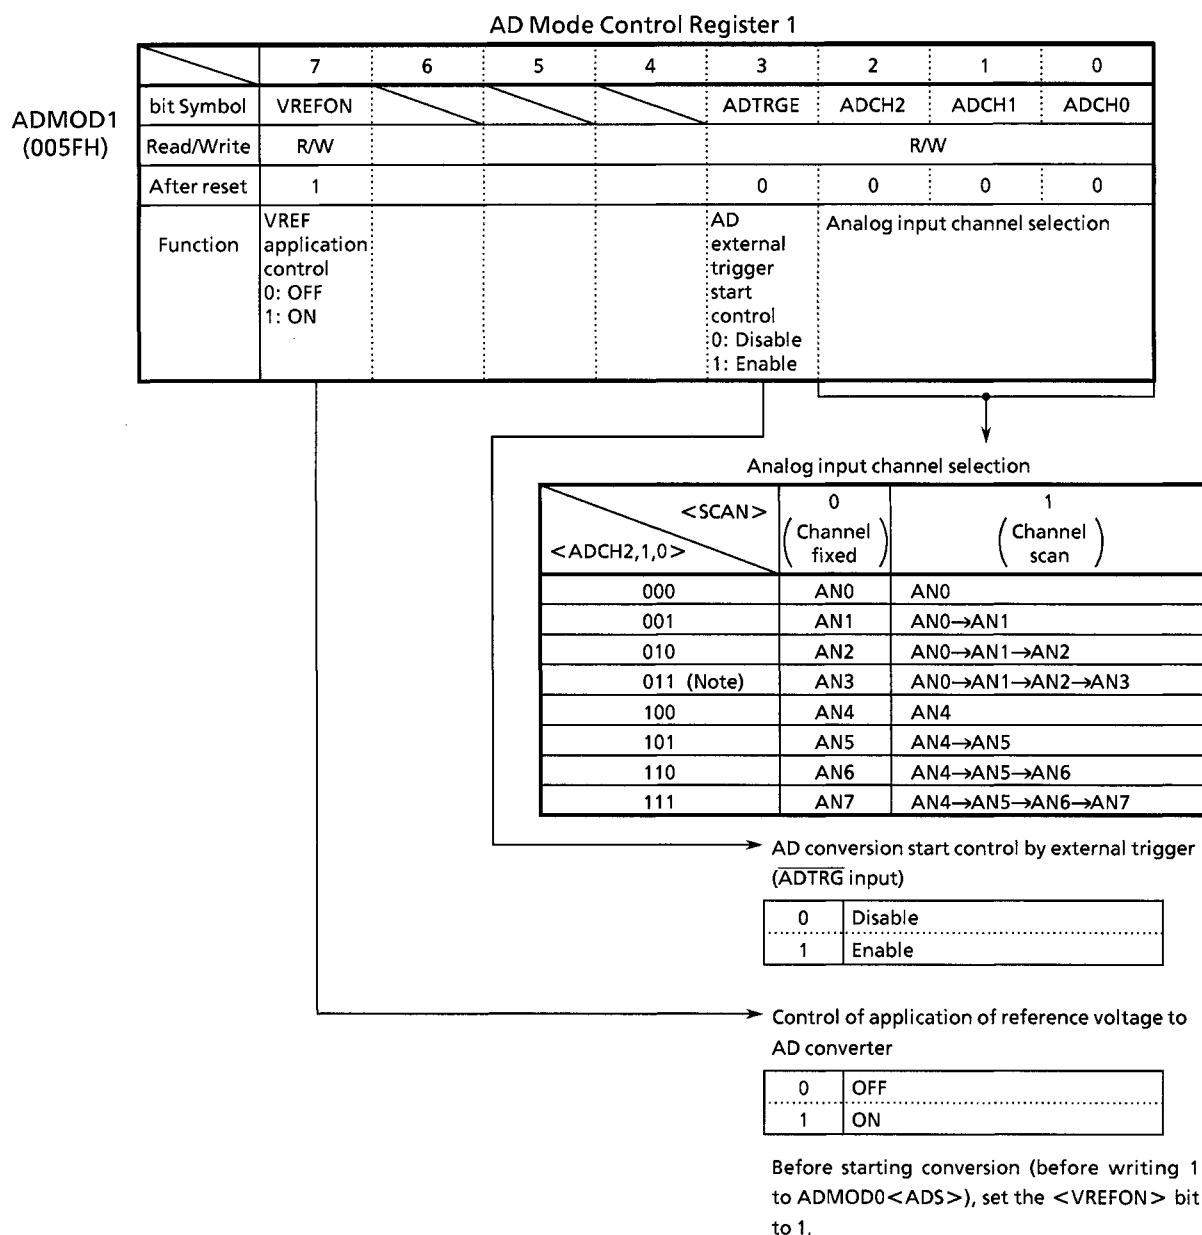

Figure 3.10.2 Register for AD Converter (1/4)

Note: As pin AN3 also functions as the $\overline{\text{ADTRG}}$ input pin, do not set <ADCH2 to 0> = 011 when using $\overline{\text{ADTRG}}$ with <ADTRGE> set to 1.

Figure 3.10.2 Register for AD Converter (2/4)

AD Conversion Data Lower Register 0/4								
	7	6	5	4	3	2	1	0
ADREG04L (0060H)	bit Symbol	ADR01	ADR00					ADR0RF
	Read/Write	R						R
	After reset	Undefined						0
	Function	Stores lower 2 bits of AD conversion result						AD conversion data storage flag 1: Conversion result stored

AD Conversion Data Upper Register 0/4								
	7	6	5	4	3	2	1	0
ADREG04H (0061H)	bit Symbol	ADR09	ADR08	ADR07	ADR06	ADR05	ADR04	ADR03
	Read/Write	R						
	After reset	Undefined						
	Function	Stores upper eight bits of AD conversion result.						

AD Conversion Data Lower Register 1/5								
	7	6	5	4	3	2	1	0
ADREG15L (0062H)	bit Symbol	ADR11	ADR10					ADR1RF
	Read/Write	R						R
	After reset	Undefined						0
	Function	Stores lower 2 bits of AD conversion result						AD conversion result flag 1: Conversion result stored

AD Conversion Data Upper Register 1/5								
	7	6	5	4	3	2	1	0
ADREG15H (0063H)	bit Symbol	ADR19	ADR18	ADR17	ADR16	ADR15	ADR14	ADR13
	Read/Write	R						
	After reset	Undefined						
	Function	Stores upper eight bits of AD conversion result.						

- Bits 5 to 1 are always read as 1.
- Bit 0 is the AD conversion data storage flag <ADRxRF>. When the AD conversion result is stored, the flag is set to 1. When either of the registers (ADREGxH, ADREGxL) is read, the flag is cleared to 0.

Figure 3.10.2 Register for AD Converters (3/4)

AD Conversion Result Lower Register 2/6

	7	6	5	4	3	2	1	0
bit Symbol	ADR21	ADR20						ADR2RF
Read/Write	R							R
After reset	Undefined							0
Function	Stores lower 2 bits of AD conversion result							AD conversion data storage flag 1: Conversion result stored

AD Conversion Data Upper Register 2/6

After reset	Undefined							
Function	Stores upper eight bits of AD conversion result.							

AD Conversion Data Lower Register 3/7

	7	6	5	4	3	2	1	0
bit Symbol	ADR31	ADR30						ADR3RF
Read/Write	R							R
After reset	Undefined							0
Function	Stores lower 2 bits of AD conversion result							AD conversion data storage flag 1: Conversion result stored

AD Conversion Result Upper Register 3/7

	7	6	5	4	3	2	1	0
bit Symbol	ADR39	ADR38	ADR37	ADR36	ADR35	ADR34	ADR33	ADR32
Read/Write	R							
After reset	Undefined							
Function	Stores upper eight bits of AD conversion result.							

- Bits 5 to 1 are always read as 1.
- Bit 0 is the AD conversion data storage flag <ADR_xRF>. When the AD conversion result is stored, the flag is set to 1. When either of the registers (ADREG_xH, ADREG_xL) is read, the flag is cleared to 0.

Figure 3.10.2 Register for AD Converters (4/4)

3.10.2 Description of Operation

(1) Analog reference voltage

A high level analog reference voltage is applied to the VREFH pin; a low level analog reference voltage to the VREFL pin. To perform AD conversion, the reference voltage (the difference between VREFH and VREFL) is divided by 1024 using string resistance. Then, the result of the division is compared with the analog input voltage.

To turn off the switch between VREFH and VREFL, write 0 to AD mode control register 1 ADMOD1<VREFON>. To start AD conversion from the off state, first write 1 to <VREFON>, wait 3 μ s until the internal reference voltage stabilizes (not related to the f_c), then write 1 to AD mode register ADMOD0<ADS>.

(2) Analog input channel selection

The analog input channel selection varies according to the operating mode of the AD converter.

- In analog input channel fixed mode (ADMOD0<SCAN> = 0)
Setting ADMOD1<ADCH2 to 0> selects one channel from among analog input pins AN0 to AN7.
- In analog input channel scan mode (ADMOD0<SCAN> = 1)
Setting ADMOD1<ADCH2 to 0> selects one scan mode from among eight scan modes.

Table 3.10.1 shows the analog input channel selection for each operating mode.

After a reset, ADMOD0<SCAN> is set to 0 and ADMOD1<ADCH2 to 0> is initialized to 000, thus selecting pin AN0 as the channel fixed input. Pins not used as analog input channels can be used as standard input ports.

Table 3.10.1 Analog Input Channel Selection

<ADCH2 to 0>	Channel fixed <SCAN> = "0"	Channel scan <SCAN> = "1"
000	AN0	AN0
001	AN1	AN0→AN1
010	AN2	AN0→AN1→AN2
011	AN3	AN0→AN1→AN2→AN3
100	AN4	AN4
101	AN5	AN4→AN5
110	AN6	AN4→AN5→AN6
111	AN7	AN4→AN5→AN6→AN7

(3) Starting AD conversion

To start AD conversion, write 1 to AD mode control register 0 ADMOD0<ADS> or AD mode control register 1 ADMOD1<ADTRGE> and input a falling edge on the $\overline{\text{ADTRG}}$ pin. When AD conversion starts, the AD conversion busy flag ADMOD0<ADBF> is set to 1, indicating AD conversion is in progress.

Writing 1 to <ADS> during AD conversion restarts conversion. At that time, to determine whether the AD conversion results are preserved, check the conversion data storage flag ADREGxL<ADRxRF>.

During AD conversion, inputting a falling edge to the $\overline{\text{ADTRG}}$ pin is ignored.

(4) AD conversion modes and AD conversion end interrupt

The four AD conversion modes are:

- Channel fixed single conversion mode
- Channel scan single conversion mode
- Channel fixed repeat conversion mode
- Channel scan repeat conversion mode

AD mode control register 0 ADMOD0<REPET>, <SCAN> selects the AD mode.

Completion of AD conversion triggers the AD conversion end INTAD interrupt request. Also, ADMOD0<EOCF> is set to 1 to indicate that AD conversion is complete.

[1] Channel fixed single conversion mode

Setting ADMOD0<REPET>, <SCAN> to 00 sets conversion channel fixed single conversion mode.

In this mode, one specified channel is converted once only. When the conversion is complete, the ADMOD0<EOCF> flag is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

[2] Channel scan single conversion mode

Setting ADMOD0<REPET>, <SCAN> to 01 sets conversion channel scan single conversion mode.

In this mode, the specified scan channels are converted once only. When scan conversion is complete, ADMOD0<EOCF> is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

[3] Channel fixed repeat conversion mode

Setting ADMOD0<REPET>, <SCAN> to 10 sets conversion channel fixed repeat conversion mode.

In this mode, one specified channel is converted repeatedly. When conversion is complete, ADMOD0<EOCF> is set to 1 and ADMOD0<ADBF> is not cleared to 0 but held at 1. The INTAD interrupt request generation timing is selected by ADMOD0<ITM0>.

Setting <ITM0> to 0 generates an interrupt request when every AD conversion is complete.

Setting <ITM0> to 1 generates an interrupt request when every fourth conversion is complete.

[4] Channel scan repeat conversion mode

Setting ADMOD0<REPET>, <SCAN> to 11 sets conversion channel scan repeat conversion mode.

In this mode, the specified scan channels are converted repeatedly. When each scan conversion is complete, ADMOD0<EOCF> is set to 1 and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to 0 but held at 1.

To stop conversion in a repeat conversion mode (mode [3] or [4]), write 0 to ADMOD0<REPET>. After the current conversion is complete, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to 0.

Switching to a halt state (IDLE2, IDLE1, or STOP) immediately stops the AD converter even with AD conversion still in progress. In repeat conversion modes (modes [3] and [4]), after the halt is released, conversion restarts from the beginning. In single conversion modes (modes [1] and [2]), conversion does not restart (the converter remains stopped).

Table 3.10.2 shows the relationship between AD conversion modes and interrupt requests.

Table 3.10.2 Relationship Between AD Conversion Modes and Interrupt Requests

Mode	Interrupt request generation	ADMOD0		
		<ITM0>	<REPET>	<SCAN>
Channel fixed single conversion mode	After completion of conversion	X	0	0
Channel scan single conversion mode	After completion of scan conversion	X	0	1
Channel fixed repeat conversion mode	Every conversion	0	1	0
	Every fourth conversion	1		
Channel scan repeat conversion mode	After completion of every scan conversion	X	1	1

X: Don't care

(5) AD conversion time

84 states (7 μ s @ $f_c = 24$ MHz) are required for AD conversion of one channel.

(6) Storing and reading AD conversion result

The AD conversion data upper and lower registers (ADREG04H/L to ADREG37H/L) store the AD conversion results. (ADREG04H/L to ADREG37H/L are read-only registers.)

In channel fixed repeat conversion mode, the conversion results are stored successively in registers ADREG04H/L to ADREG37H/L. In other modes, the AN0 and AN4, AN1 and AN5, AN2 and AN6, and AN3 and AN7 conversion results are stored in ADREG04H/L, ADREG15H/L, ADREG26H/L, and ADREG37H/L respectively.

Table 3.10.3 shows the correspondence between analog input channels and AD conversion result registers.

Table 3.10.3 Correspondence Between Analog Input Channels and AD Conversion Result Registers

Analog input channel (port A)	AD conversion result register	
	Conversion modes other than at right	Channel fixed repeat conversion mode (every 4th conversion)
AN0	ADREG04H/L	
AN1	ADREG15H/L	
AN2	ADREG26H/L	
AN3	ADREG37H/L	
AN4	ADREG04H/L	
AN5	ADREG15H/L	
AN6	ADREG26H/L	
AN7	ADREG37H/L	

The AD conversion data storage flag <ADRxRF> uses bit 0 of the AD conversion data lower register. The storage flag indicates whether the AD conversion result register was read or not. When a conversion result is stored in the AD conversion result register, the flag is set to 1. When either of the AD conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to 0.

Reading the AD conversion result also clears the AD conversion end flag ADMOD0<EOCF> to 0.

Setting example:

- [1] Convert the analog input voltage at the AN3 pin and write the result to memory address 0800H using the AD interrupt (INTAD) processing routine.

Main routine setting:

7 6 5 4 3 2 1 0

INTE0AD	←	1 1 0 0 - - - -	Enable INTAD and set level to 4.
ADMOD1	←	1 X X X 0 0 1 1	Set analog input channel to pin AN3.
ADMOD0	←	X X 0 0 0 0 0 1	Start conversion in channel fixed single conversion mode.

Interrupt routine processing example:

WA	←	ADREG37	Read value of ADREG37L and ADREG37H to general-purpose register WA (16 bits).
WA	>>	6	Shift contents read in WA six times to right and zero-fill upper bits.
(0800H)	←	WA	Write contents of WA to memory address 0800H.

- [2] This example repeatedly converts the analog input voltages at the three pins AN0 to AN2, using channel scan repeat conversion mode.

INTE0AD	←	1 0 0 0 - - - -	Disable INTAD.
ADMOD1	←	1 X X X 0 0 1 0	Set pins AN0 to AN2 as analog input channels.
ADMOD0	←	X X 0 0 0 1 1 1	Start conversion in channel scan repeat conversion mode.

Note: X : Don't care - : No change

3.11 CAN Controller

(1) Overview

- Supports CAN version 2.0B
- Supports standard format and Extended format
- Supports data frames and remote frames in both formats
- 16 Mailboxes (15 Receive & Transmit + 1 Receive only)
- Baud rate up to 1Mbps on the CAN bus (at operation frequency 20 to 24 MHz)
- Programmable baud rate with bit time parameter
- Built in baud rate prescaler
- 2 selectable mechanisms for internal arbitration of transmit messages
 - [1] mailbox number
 - [2] identifier priority
- Time stamp for receive and transmit messages
- Operation mode
 - [1] Normal operation mode
 - [2] Configuration mode
 - [3] Sleep mode (Wake up on CAN bus activity or CPU access)
 - [4] Halt mode
 - [5] Test loopback mode (stand alone operation enabled by self acknowledge)
 - [6] Test error mode (Write enabled to error counter)
- Message acceptance filter
 - [1] Programmable global mask for mailboxes 0 to 14
 - [2] Programmable local mask for mailbox 15
- Acceptance mask bit for identifier extended bit
- Flexible interrupt structure (3 interrupts)
 - [1] Receive interrupt: INTCR
 - [2] Transmit interrupt: INTCT
 - [3] Global interrupt: INTCG (includes warning level, error passive, bus off, etc.)

(2) Nomenclature

- R/W Read and write access by the CPU
- R Read access by the CPU
- W Write access by the CPU
- R/S Read access and set (write with 1) by the CPU
- R/C Read access and clear (write with 1) by the CPU
- The mailbox RAM symbol “–” following a Reset indicates that the initial value is indeterminate.
- The mailbox RAM bit Symbol “\” denotes blank bits. The values of these bits are indeterminate when read.
- The control register bit Symbol “\” denotes reserved bits. They indicate that value is indeterminate when read.
Always write “0” when write.

(3) Architecture

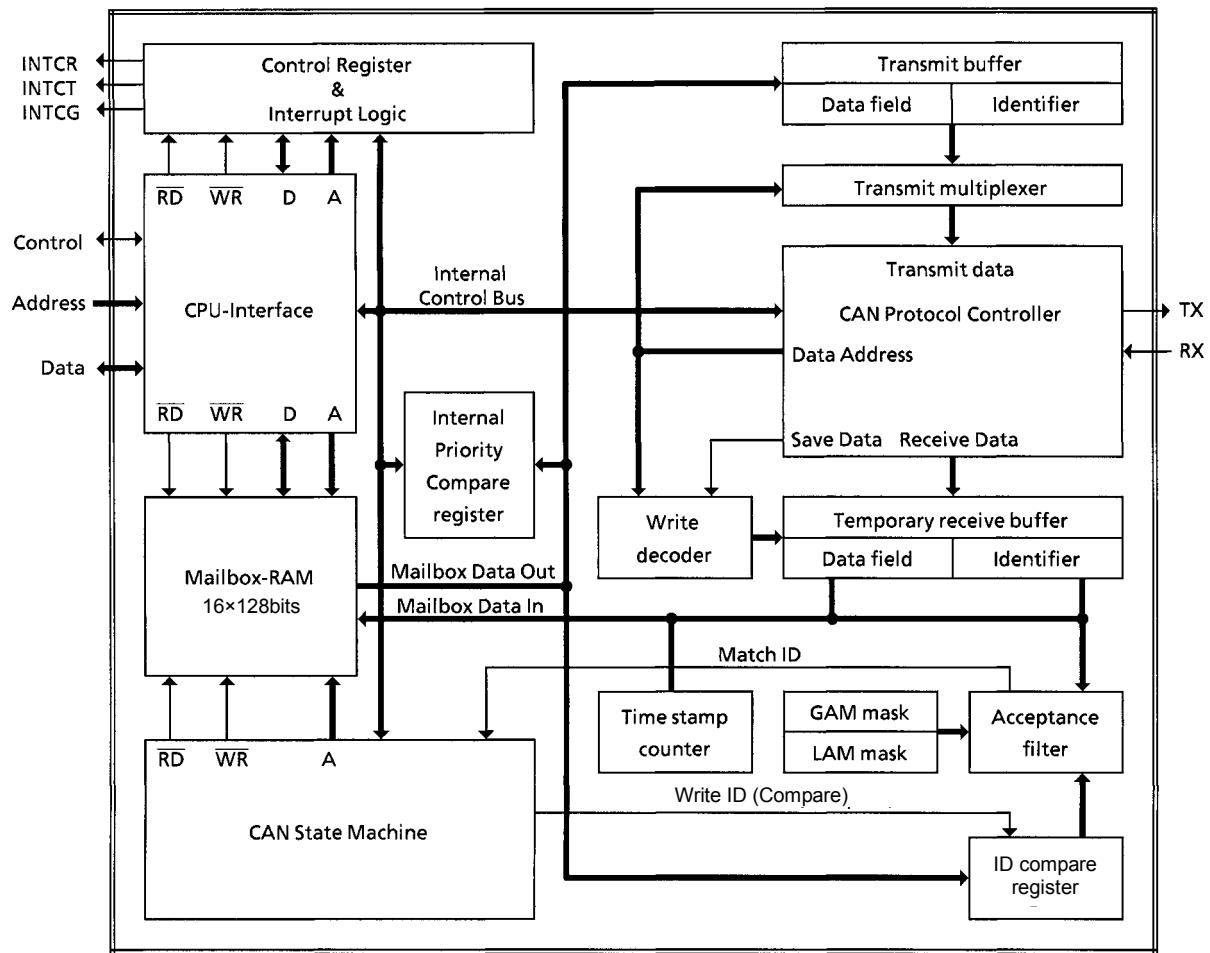

Figure 3.11.1 Block Diagram of CAN Controller

(4) CAN bus interface

The interface to the CAN bus is a simple two-wire line, consisting of an input pin RX and an output pin TX. This CAN bus interface is suitable for operation with CAN bus transceivers based on ISO/DIS 11898.

3.11.1 Memory Map

The mailboxes and control registers used by the CAN are mapped to the memory locations shown below.

Table 3.11.1 CAN Mailboxes and Control Registers

Address	Register	Description
002200H *	MB0	Mailbox RAM
:	:	
0022FFH *	MB15	
002300H	MC	Mailbox Configuration Register
002302H	MD	Mailbox Direction Register
002304H *	TRS	Transmit Request Set Register
002306H *	—	(Reserved)
002308H *	TA	Transmission Acknowledge Register
00230AH *	—	(Reserved)
00230CH *	RMP	Receive Message Pending Register
00230EH *	RML	Receive Message Lost Register
002310H	LAM0 (high)	Local Acceptance Mask Register 0 (bit 28 to 16)
002312H	LAM1 (low)	Local Acceptance Mask Register 1 (bit 15 to 0)
002314H	GAM0 (high)	Global Acceptance Mask Register 0 (bit 28 to 16)
002316H	GAM1 (low)	Global Acceptance Mask Register 1 (bit 15 to 0)
002318H	MCR	Master Control Register
00231AH	GSR	Global Status Register
00231CH	BCR1	Bit Configuration Register 1
00231EH	BCR2	Bit Configuration Register 2
002320H *	GIF	Global Interrupt Flag Register
002322H	GIM	Global Interrupt Mask Register
002324H *	MBTIF	Mailbox Transmit Interrupt Flag Register
002326H *	MBRIF	Mailbox Receive Interrupt Flag Register
002328H	MBIM	Mailbox Interrupt Mask Register
00232AH	CDR	Change Data Request Register
00232CH *	RFP	Remote Frame Pending Register
00232EH *	CEC	CAN Error Counter Register
002330H	TSP	Time Stamp Counter Prescaler Register
002332H *	TSC	Time Stamp Counter Register

Note1: * Read- modify-write prohibited.

Note2: Do not access the reserved address.

3.11.2 Mailboxes

The mailbox is configured with RAM to store identifiers and transmit/receive data, which can be accessed by the CAN controller and the CPU. The CPU controls the CAN controller by modifying the contents of the mailboxes and control registers. The contents of the mailboxes and control registers are used to perform the functions of acceptance filtering, transmit message and interrupt handling.

In order to initiate a transfer, the transmission request bit has to be written to the corresponding register. The entire transmission procedure is done then without any CPU involvement. If a mailbox has been configured as receive messages the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

The mailbox module provides 16 mailboxes, each of which has 8 bytes long data, 29-bit identifier and several control bits. Each mailbox is 16 bytes in size. Each mailbox, except the last one, can be set for either transmit or receive operation.

Mailbox 15 is a receive-only mailbox with a special acceptance mask designed to allow groups of different message identifiers to be received.

The receive-only mailbox 15 masks all bits when receiving a message whose ID does not correspond to any of the mailboxes 0 to 14.

In addition, when using mailbox 15 as a usual receiving mailbox, the automatic remote frame response function cannot be used. Set <RFH> bit to 0 to disable automatic remote frame response. In this case, each time a message is received, the ID of all mailboxes is checked by software. If the ID is rewritten to a different ID from that which was originally received, the received data is invalid. Once mailbox prohibit (MC=0) is set, after waiting maximum frame length, set the correct ID again.

Address	Mailboxes
2200H to 220FH	MB0 (Used for transmit/receive)
2210H to 221FH	MB1 (Used for transmit/receive)
:	:
:	:
22E0H to 22EFH	MB14 (Used for transmit/receive)
22F0H to 22FFH	MB15 (Used for receive-only)

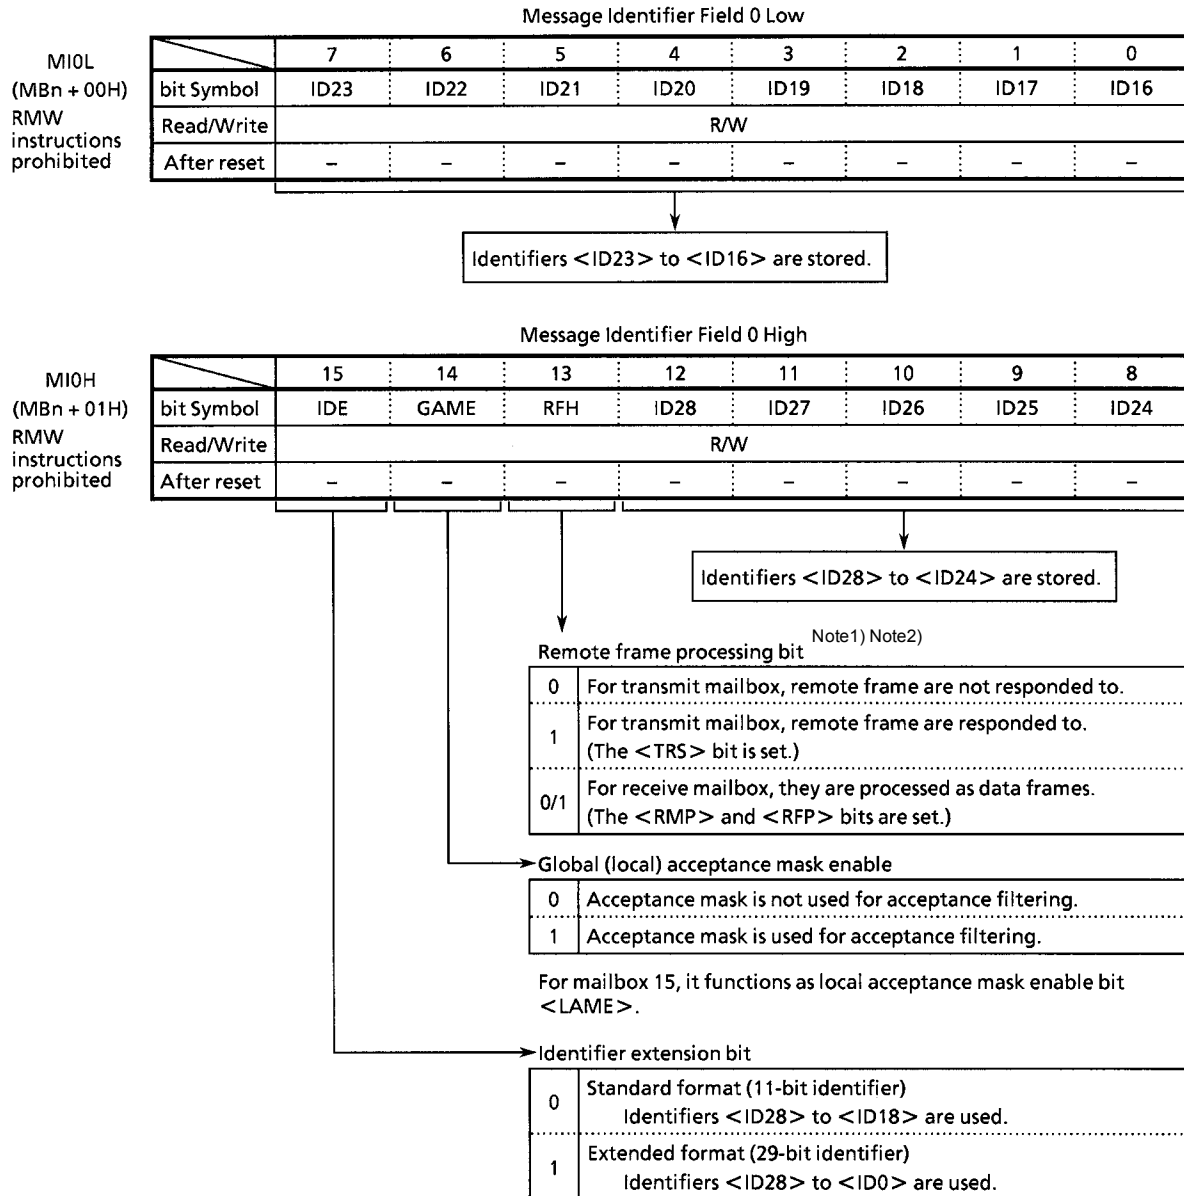

Each mailbox is configured as shown below.

(Mailbox "n")	b15	b0	
MBn + 00H	MI0		(Message identifier field 0)
02H	MI1		(Message identifier field 1)
04H	MCF		(Message control field)
06H	D1	D0	(Data field 0, 1)
08H	D3	D2	(Data field 2, 3)
0AH	D5	D4	(Data field 4, 5)
0CH	D7	D6	(Data field 6, 7)
0EH	TSV		(Time stamp value)

Note: MBn = 2200H + n × 10H

The components of each mailbox are explained in the following pages.

Message Identifier Field 0 (MI0)

The priority of a message ID becomes so high that 0 continues from the MSB (<ID28> bit) of ID.

Note1: When the receive-only mailbox MB15 is used as a usual receiving mailbox, the automatic remote frame response function cannot be used. The remote frame processing bit <RFH> is set to "0".

Note2: When the ID of the received remote frame corresponds to the ID of the transmission mailbox <RFH> = "1" and <GAME> = "1", the ID of the remote frame is overwritten to this mailbox. Thereafter, it responds by automatically applying the overwritten ID.

Message Identifier Field 1 (MI1)

Message Identifier Field 1 Low

MI1L (MBn + 02H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	ID7	ID6	ID5	ID4	ID3	ID2	ID1	ID0
	Read/Write	R/W							
	After reset	-	-	-	-	-	-	-	-

Identifiers <ID7> to <ID0> are stored.

Message Identifier Field 1 High

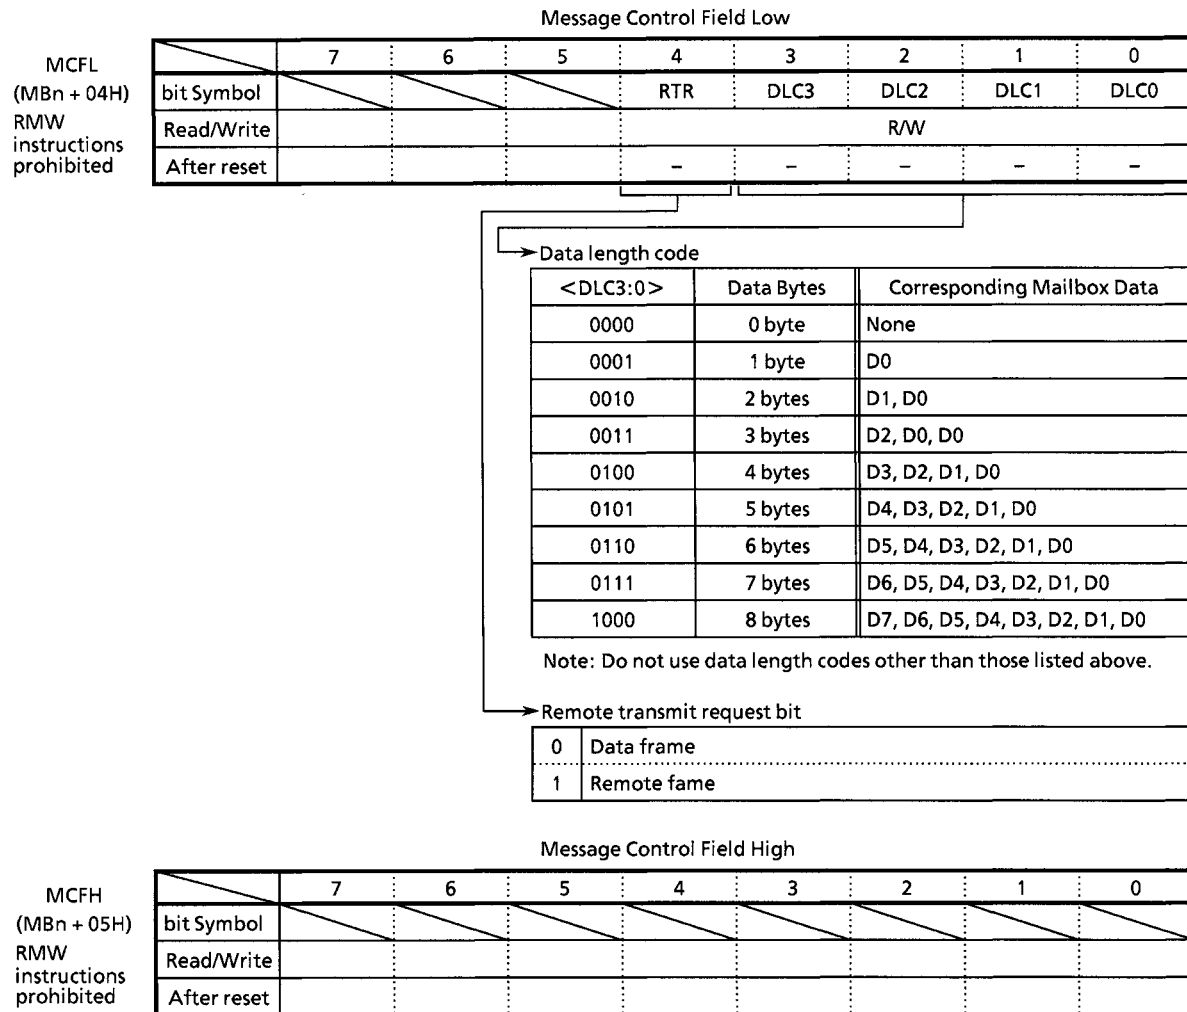

MI1H (MBn + 03H) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	ID15	ID14	ID13	ID12	ID11	ID10	ID9	ID8
	Read/Write	R/W							
	After reset	-	-	-	-	-	-	-	-

Identifiers <ID15> to <ID8> are stored.

Note1: For standard format, identifiers <ID17> to <ID0> are indeterminate.

Note2: Set the mailbox ID at initial configuration. Once a mailbox has been enabled, when writing to the MI0 or MI1 field of the mailbox, reset the <MC> bit, and after a mailbox has been prohibited by the CAN controller, wait the maximum frame length time before executing the operation.

Message Control Field (MCF)

Note: There is no necessity for initial configuration of receive mailboxes. RTR and DLC of the received message are stored in the MCF register. Please set transmit mailboxes at the initial configuration.

Data field (D0 to D7)

This is a read/write register that stores up to 8 bytes of transmit/receive data. However, in the case of receive mailboxes, the write access to the data field is disabled.

For transmit, data in a length of bytes set by the mailbox's data length code is transmitted.

For receive, the data length code in the receive message is copied to the mailbox's data length code, so that the byte in a length equal to this data length code is received as valid data.

Data field 0									
D0 (MBn + 06H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	D07	D06	D05	D04	D03	D02	D01	D00

	bit Symbol	D47	D46	D45	D44	D43	D42	D41	D40
	Read/Write	R/W							
	After reset	–	–	–	–	–	–	–	–
Data field 5									
D5 (MBn + 0BH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	D57	D56	D55	D54	D53	D52	D51	D50
	Read/Write	R/W							
	After reset	–	–	–	–	–	–	–	–
Data field 6									
D6 (MBn + 0CH) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	D67	D66	D65	D64	D63	D62	D61	D60
	Read/Write	R/W							
	After reset	–	–	–	–	–	–	–	–
Data field 7									
D7 (MBn + 0DH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	D77	D76	D75	D74	D73	D72	D71	D70
	Read/Write	R/W							
	After reset	–	–	–	–	–	–	–	–

Time Stamp Value (TSV)

		Time Stamp Value Low							
TSVL (MBn + 0EH)		7	6	5	4	3	2	1	0
	bit Symbol	TSV7	TSV6	TSV5	TSV4	TSV3	TSV2	TSV1	TSV0
	Read/Write	R							
	After reset	–	–	–	–	–	–	–	–

		Time Stamp Value High							
TSVH (MBn + 0FH)		15	14	13	12	11	10	9	8
	bit Symbol	TSV15	TSV14	TSV13	TSV12	TSV11	TSV10	TSV9	TSV8
	Read/Write	R							
	After reset	–	–	–	–	–	–	–	–

This is a 16-bit read-only register into which the value of the time stamp counter is loaded when data is successfully transmitted or received.

The counter value is not loaded into this register when transmit or receive operations fail.

Maximum frame length

Rewrite message ID field after MCn is prohibited and one frame time passes.

General one frame time is as follows:

N means the number of data byte (0-8 byte).

- Standard frame format (at data frame) = $(44 + 8N) \times 1$ bit time
- Extended frame format (at data frame) = $(64 + 8N) \times 1$ bit time

Furthermore, the maximum frame length to which bit stuffing applies is as follows:

Since the maximum number of bits is eight byte data of the extended frame format,

$$64\text{-bit(fixed length)} + 64\text{-bit (number of data bytes)} = 128\text{-bit.}$$

Moreover, the bit stuffing rule is not applied to

EOF + ACK field + CRC delimiter = 10-bit,

Therefore the maximum number of bits to which the bit stuffing rule applies is

$$128\text{-bit} - 10\text{-bit} = 118\text{-bit length.}$$

(It is calculated on the assumption of the longest case of insertion of the stuffing bit in the CRC field.)

At the bit stuffing rule, as a reversing bit is inserted when the same level is 5-bit successive, the maximum inserted number of bits is

$$118\text{-bit} \div 5 \rightarrow 24\text{-bit.}$$

Hence, the maximum frame length is

$$128\text{-bit} + 24\text{-bit} = 152\text{-bit.}$$

Therefore, when the message ID field is rewritten at a baud-rate of 500kbps, is the necessary waiting time is:

$$152\text{-bit} \times 2 \text{ us} = 304 \text{ us}$$

3.11.3 Control Registers

(1) Mailbox control registers

Mailbox configuration register (MC)

		Mailbox Configuration Register Low							
MCL (2300H)		7	6	5	4	3	2	1	0
	bit Symbol	MC7	MC6	MC5	MC4	MC3	MC2	MC1	MC0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

		Mailbox Configuration Register High							
MCH (2301H)		15	14	13	12	11	10	9	8
	bit Symbol	MC15	MC14	MC13	MC12	MC11	MC10	MC9	MC8
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Each bit corresponds to mailboxes 0 through 15.

Each mailbox can be enabled or disabled.

When $\langle MC_n \rangle = 1$, access to mailbox “n” is enabled.

When $\langle MC_n \rangle = 0$, access to mailbox “n” is disabled.

If, during CAN controller transmission, $\langle MC_n \rangle = 0$, access may be permitted depending on the transmission stage. In this case, there is the possibility of conflict between the mailbox transmit/receive complete flag and the transmit/receive interrupt flag.

Set the mailbox ID at initial configuration. After disabling a mailbox by resetting the $\langle MC \rangle$ bit, wait the maximum frame length time before rewriting to the MI0 or MI1 field of the mailbox which is permitted.

The transmit mailbox data and control fields can be accessed for write at any time. However, in the case of transmit mailboxes where the $\langle RFH \rangle$ bit is set, the write access to the message control field is enabled when the $\langle MC \rangle$ bit is reset.

Mailbox direction register (MD)

		Mailbox Direction Register Low							
MDL (2302H)		7	6	5	4	3	2	1	0
	bit Symbol	MD7	MD6	MD5	MD4	MD3	MD2	MD1	MD0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

		Mailbox Direction Register High							
MDH (2303H)		15	14	13	12	11	10	9	8
	bit Symbol	MD15	MD14	MD13	MD12	MD11	MD10	MD9	MD8
	Read/Write	R	R/W						
	After reset	1	0	0	0	0	0	0	0

Each bit corresponds to mailbox 0 through 15.

Each mailbox except mailbox 15 can be directed for transmit or receive.

When $\langle MDn \rangle = 0$, the mailbox MBn is directed for transmit.

When $\langle MDn \rangle = 1$, the mailbox MBn is directed for receive.

Mailbox 15 is a receive-only mailbox, so that $\langle MD15 \rangle$ bit is fixed to 1. This bit can only be read; you cannot write to it.

MD registers are set at initial configuration. When the setting is changed while transmitting or receiving, the following operations occur.

- (1) When changing to $\langle MDn \rangle = 0$ (transmission) while receiving.

Reception of the message currently being received continues, and after the reception is completed, the $\langle RMPn \rangle$ bit is set to 1. However, the $\langle MBRIFn \rangle$ flag is not set even if $\langle MBIMn \rangle$ is set to 1 (interrupt enabled), and the receive interrupt is not generated.

- (2) When changing to $\langle MDn \rangle = 1$ (reception) while transmitting.

Transmission of the message currently being transmitted continues, and after the transmission is completed, $\langle TAn \rangle$ bit is set to 1. However, the $\langle MBTIFn \rangle$ flag is not set even if $\langle MBIMn \rangle$ is set to 1 (interrupt enabled), and the transmit interrupt is not generated.

(2) Transmit control registers

Transmission request set register (TRS)

Transmission Request Set Register Low									
TRSL (2304H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	TRS7	TRS6	TRS5	TRS4	TRS3	TRS2	TRS1	TRS0
	Read/Write	R/S							
	After reset	0	0	0	0	0	0	0	0

Transmission Request Set Register High									
TRSH (2305H) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol		TRS14	TRS13	TRS12	TRS11	TRS10	TRS9	TRS8
	Read/Write	R/S							
	After reset		0	0	0	0	0	0	0

Each bit corresponds to mailboxes 0 through 15. Since mailbox 15 is a receive-only mailbox, bit 15 is nonexistent.

If after writing data and identifier to mailbox “n” that has been set for transmit (<MDn> = 0), the <TRS_n> bit is set when the said mailbox is enabled (<MCn> = 1), a message is transmitted from mailbox “n”. If there are multiple transmit requests, messages are transmitted sequentially. The order in which messages are transmitted depends on the master control register MCR bit 3 <MTOS>.

If <MTOS> bit is set to “0”, the mailbox with the lower number has the higher priority. For example: if the mailboxes MB0, MB2 and MB5 are configured for transmission and the corresponding TRS bits are set, then the messages will be transmitted in the following order: MB0, MB2 and MB5. If a new transmission request is set for MB0 during the processing of MB2 then in the next internal arbitration-run MB0 will be selected for the next transmission. This will also happen, when the CAN controller loses arbitration while transmitting MB2. In this case, MB0 will be sent at the next opportunity instead of MB2.

If <MTOS> bit is set to “1”, the priority of the identifier stored in the mailbox will determine the sending order. The mailbox with the higher-priority identifier will be sent first. In case of a lost arbitration on the CAN bus line, a new internal arbitration run will be started and the message with the highest priority will be sent at the next possible time.

The <TRS_n> bit is reset when transmit has succeeded.

If transmit has failed, transmit is retried repeatedly until it succeeds.

When the <TRS_n> bit is 1, the write access to the corresponding mailbox is denied.

The <TRS_n> bit cannot be set from the CPU if mailbox “n” is set for receive.

When mailbox “n” is set for transmit, the <TRS_n> bit is set by writing a 1 from the CPU and is reset by the internal logic. Writing a 0 from the CPU has no effect.

(3) Receive control registers

The identifier of each incoming message is compared with the identifiers held in the mailboxes that have been set for receive operation. The comparison of the identifiers depends on the value of the global/local acceptance mask enable bits <GAME>/<LAME> in the mailbox and the data held in the global/local acceptance mask registers GAM/LAM.

When a matching identifier is detected, the received identifier, control bits, and data bytes are written to the mailbox that has matched. At this time, the corresponding receive message pending bit <RMPn> is set and a receive successful interrupt is generated if it has been enabled. Once a matching identifier is found, no other identifiers are compared.

If no match is detected, the message is rejected.

The CPU must reset the <RMPn> bit after reading the data. If a second message is received for this mailbox when the <RMPn> bit has already been set, the corresponding receive message lost bit <RMLn> is set. In this case, the data stored in mailbox “n” is overwritten with the new data. In this case, a global interrupt (receive message lost) is generated if it has been enabled.

Receive-only mailbox

Only if the identifier of a received message does not match any identifiers of the mailboxes 0 through 14 is the identifier compared with the identifier of the receive-only mailbox 15. When a matching identifier is detected, the contents of the received message are written to the mailbox 15.

Receive message pending register (RMP)

Receive Message Pending Register Low									
RMPL (230CH) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	RMP7	RMP6	RMP5	RMP4	RMP3	RMP2	RMP1	RMP0
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Receive Message Pending Register High									
RMPH (230DH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	RMP15	RMP14	RMP13	RMP12	RMP11	RMP10	RMP9	RMP8
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Each bit corresponds to mailbox 0 through 15.

When a message is received and its content is stored in mailbox “n”, the <RMPn> bit is set.

If a second message is received by mailbox “n” for which the <RMPn> bit has been set, mailbox “n” is overwritten with the new data. In this case, the corresponding <RMLn> bit is set.

The <RMPn> bit is set by the internal logic and is reset by writing a 1 to the <RMPn> bit from the CPU. Writing a 0 from the CPU has no effect.

Receive message lost register (RML)

		Receive Message Lost Register Low							
RMLL (230EH) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	RML7	RML6	RML5	RML4	RML3	RML2	RML1	RML0
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

		Receive Message Lost Register High							
RMLH (230FH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	RML15	RML14	RML13	RML12	RML11	RML10	RML9	RML8
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Each bit corresponds to mailbox 0 through 15.

If a second message is received by mailbox “n” for which the <RMPn> bit has been set, mailbox “n” is overwritten with the new data and the <RMLn> bit is set.

The <RMLn> bit is set by the internal logic and is reset by writing a 1 to the <RMPn> bit from the CPU. Writing a 0 to <RMPn> bit and writing a 1 or 0 to <RMLn> bit from the CPU have no effect.

(4) Handling of remote frames

If a remote frame is received, it is compared with the identifiers of all mailboxes. The comparison of identifiers depends on the value of the global/local acceptance mask enable bits <GAME>/<LAME> in the mailbox and the data held in the global/local acceptance mask registers GAM/LAM.

If a received remote frame matches the identifier of a mailbox that is set for transmit and the <RFH> bit for that mailbox is set, the <TRSn> bit is set in order to send a message in response to the remote frame. Even when there is a matching identifier, if the <RFH> bit for that mailbox is reset (even though it may be a transmit mailbox), the remote frame is not responded to.

If there is a matching identifier and this mailbox is set for receive, the remote frame is processed as data frame, in which case the <RMP> and <RFP> bits are set.

Once a matching identifier is found, no other identifiers are compared.

Table 3.11.2 Operation when Remote Frame is Received

ID	Mailbox	<RFH> bit	Handling of Remote Frame
Matched	Transmit	0	Not responded to.
		1	Responded to. (<TRS> bit is set) ^(Note)
	Receive	1/0	Not responded to. Processed as data frame. (<RMP> and <RFP> bits are set.)
Unmatched	Transmit/Receive	1/0	Not responded to.

Note: When the ID matches a <GAME>=1 mailbox, the mailbox ID is overwritten with the remote frame ID and automatically responds to this new ID.

Remote frame pending register (RFP)

Remote Frame Pending Register Low									
RFPL (232CH) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	RFP7	RFP6	RFP5	RFP4	RFP3	RFP2	RFP1	RFP0
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Remote Frame Pending Register High									
RFPH (232DH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	RFP15	RFP14	RFP13	RFP12	RFP11	RFP10	RFP9	RFP8
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

When a remote frame is received by mailbox “n” set for receive, the corresponding <RFPn> and <RMPn> bits are set. The <RFPn> bit is reset by writing a “1” to the <RMPn> bit. Writing a “0” has no effect. Also, the <RFPn> bit is reset automatically when the remote frame received in mailbox “n” is overwritten by a newly received data frame.

(5) Acceptance filter

The global acceptance mask registers GAM0 and GAM1 are used for filtering messages when the <GAME> bit for mailboxes 0 through 14 is set to 1. An incoming message is stored in the first mailbox with a matching identifier. Only if there is no matching identifier in the mailboxes 0 to 14 is the incoming message compared with the mailbox 15, a receive-only mailbox. The local acceptance mask registers LAM0, LAM1 are used for filtering messages when the <LAME> bit for mailbox 15 is set.

Figure 3.11.2 Acceptance Filter

Local acceptance mask registers (LAM0, LAM1)

Local Acceptance Mask Register 0 Low									
LAM0L (2310H)		7	6	5	4	3	2	1	0
	bit Symbol	LAM23	LAM22	LAM21	LAM20	LAM19	LAM18	LAM17	LAM16
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Local Acceptance Mask Register 0 High									
LAM0H (2311H)		15	14	13	12	11	10	9	8
	bit Symbol	LAM1			LAM28	LAM27	LAM26	LAM25	LAM24
	Read/Write	R/W			R/W				
	After reset	0			0	0	0	0	0

Local Acceptance Mask Register 1 Low									
LAM1L (2312H)		7	6	5	4	3	2	1	0
	bit Symbol	LAM7	LAM6	LAM5	LAM4	LAM3	LAM2	LAM1	LAM0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Local Acceptance Mask Register 1 High									
LAM1H (2313H)		15	14	13	12	11	10	9	8
	bit Symbol	LAM15	LAM14	LAM13	LAM12	LAM11	LAM10	LAM9	LAM8
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

The LAM0 and LAM1 registers are used only for filtering messages for mailbox 15. This feature allows the user to choose whether or not to locally mask any identifier bit of the incoming message for mailbox 15. Incoming messages are first checked to see if they match mailboxes 0 to 14 before being forwarded to mailbox 15.

If the <LAMn> bit is 0, messages are received only when the corresponding bit of the incoming message identifier matches that of the mailbox identifier. If the <LAMn> bit is 1, messages are received regardless of whether the corresponding bit of the incoming message identifier is 0 or 1. The GAM0 and GAM1 registers do not affect mailbox 15.

For messages in extended format, the identifier extension <IDE> bit and the whole 29 bits of the identifier are compared. For messages in standard format, only the <IDE> bit and the first 11bits of the identifier (<ID28> to <ID18>) are compared.

The <LAMI> bit (local acceptance mask identifier extension bit) is used to mask the <IDE> bit of mailbox 15.

If the <LAMI> bit is 0, messages in extended or standard format are received according to the <IDE> bit of mailbox 15.

If the <LAMI> bit is 1, messages in both extended and standard formats are received regardless of whether the <IDE> bit of mailbox 15 is 0 or 1. For messages in extended format, the whole 29bits of the mailbox identifier and the whole 29 mask bits of the LAM register are used for filtering. For messages in standard format, only the first 11bits of the mailbox identifier (<ID28> to <ID18>) and the first 11 bits of the LAM register (<LAM28> to <LAM18>) are used for filtering.

LAM0 and LAM1 are set at initial configuration. Do not change the setting of these registers while operating. If the setting is changed while receiving, the received message IDs are compared with the changed register values.

Global acceptance mask registers (GAM0, GAM1)

Global Acceptance Mask Register 0 Low

GAM0L (2314H)		7	6	5	4	3	2	1	0
	bit Symbol	GAM23	GAM22	GAM21	GAM20	GAM19	GAM18	GAM17	GAM16
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Global Acceptance Mask Register 0 High

GAM0H (2315H)		15	14	13	12	11	10	9	8
	bit Symbol	GAM1			GAM28	GAM27	GAM26	GAM25	GAM24
	Read/Write	R/W	R/W						
	After reset	0			0	0	0	0	0

Global Acceptance Mask Register 1 Low

GAM1L (2316H)		7	6	5	4	3	2	1	0
	bit Symbol	GAM7	GAM6	GAM5	GAM4	GAM3	GAM2	GAM1	GAM0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Global Acceptance Mask Register 1 High

GAM1H (2317H)		15	14	13	12	11	10	9	8
	bit Symbol	GAM15	GAM14	GAM13	GAM12	GAM11	GAM10	GAM9	GAM8
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

The GAM0 and GAM1 registers are used for filtering messages for mailbox 0 to 14.

If the <GAME> bit for mailboxes 0 to 14 is set, the GAM0 and GAM1 registers are used for incoming messages. A received message is stored in only the first mailbox with a matching identifier.

If the <GAMn> bit is 0, messages are received only when the corresponding bit of the incoming message identifier matches that of the mailbox identifier. If the <GAMn> bit is 1, messages are received regardless of whether the corresponding bit of the incoming message identifier is 0 or 1. For messages in extended format, the identifier extension <IDE> bit and the whole 29 bits of the identifier are compared. For messages in standard format, only the <IDE> bit and the first 11 bits of the identifier (<ID28> to <ID18>) are compared.

The <GAMI> bit (global acceptance mask identifier extension bit) is used to mask the <IDE> bits of mailbox 0 to 14.

If the <GAMI> bit is 0, messages in extended or standard format are received according to the <IDE> bits of mailbox 0 to 14.

If the <GAMI> bit is 1, messages in both extended and standard formats are received regardless of whether the <IDE> bits of mailbox 0 to 14 are 0 or 1. For messages in extended format, the whole 29 bits of the mailbox identifier and the whole 29 mask bits of the GAM register are used for filtering. For messages in standard format, only the first 11bits of the mailbox identifier (<ID28> to <ID18>) and the first 11 bits of the GAM register (<GAM28> to <GAM18>) are used for filtering.

GAM0 and GAM1 are set at initial configuration. Do not change the setting of these registers while operating. If the setting is changed while receiving, the received message IDs are compared with the changed register values.

(6) Control registers

Master control register (MCR)

Master Control Register Low								
MCR (2318H)	7	6	5	4	3	2	1	0
	CCR	SMR	HMR	WUBA	MTOS		TSCC	SRES
	R/W						W	
	1	0	0	0	0		0	0

Master Control Register High								
MCRH (2319H)	15	14	13	12	11	10	9	8
							TSTLB	TSTERR
							R/W	
							0	0

TSTLB: Test Loopback

0: Cancels the test loopback mode. (Normal operation)

1: Requests the test loopback mode.

This mode supports stand-alone operation.

TSTERR: Test Error

0: Cancels the test error mode. (Normal operation)

1: Requests the test error mode.

In this mode it is possible to write the error counter register CEC.

CCR: Change Configuration Request

0: Cancels the configuration mode. (Normal operation)

1: Request the configuration mode.

This mode allows for writing to the bit configuration registers BCR1, BCR2.

SMR: Sleep Mode Request

0: The sleep mode is not requested. (Normal operation)

1: Requests the sleep mode.

When this mode is entered, the CAN controller clock stops oscillating and the error counter and transmit requests are cleared.

HMR: Halt Mode Request

0: Cancels the halt mode. (Normal operation)

1: Requests the halt mode.

When this mode is entered, the CAN controller no longer transmits and receives messages. It only sends error and acknowledge flags.

WUBA: Wake Up on Bus Activity

0: Wakes up the module only by detecting a write access to the MCR register.

1: Wakes up the module when active bus state is detected or detecting a write access to the MCR register.

MTOS: Mailbox Transmission Order Select

- 0: Mailbox transmission order by mailbox number. The mailbox with the lower number will be sent first.
- 1: Mailbox transmission order by identifier priority. The mailbox with the higher priority identifier will be sent first.

TSCC: Time Stamp Counter Clear

- 0: No effect
- 1: The time stamp counter will be cleared.

Note 1: This is a write-only bit; it is always 0 when read.

Note 2: The time stamp counter is also cleared by a write to the TSP register, or writing a 0 to the TSC register.

SRES: Software Reset

- 0: No effect
- 1: Resets the CAN controller in software. All internal registers are initialized.

Note: This is a write-only bit; it is always 0 when read.

Bit configuration register 1 (BCR1)

Bit Configuration Register 1 Low

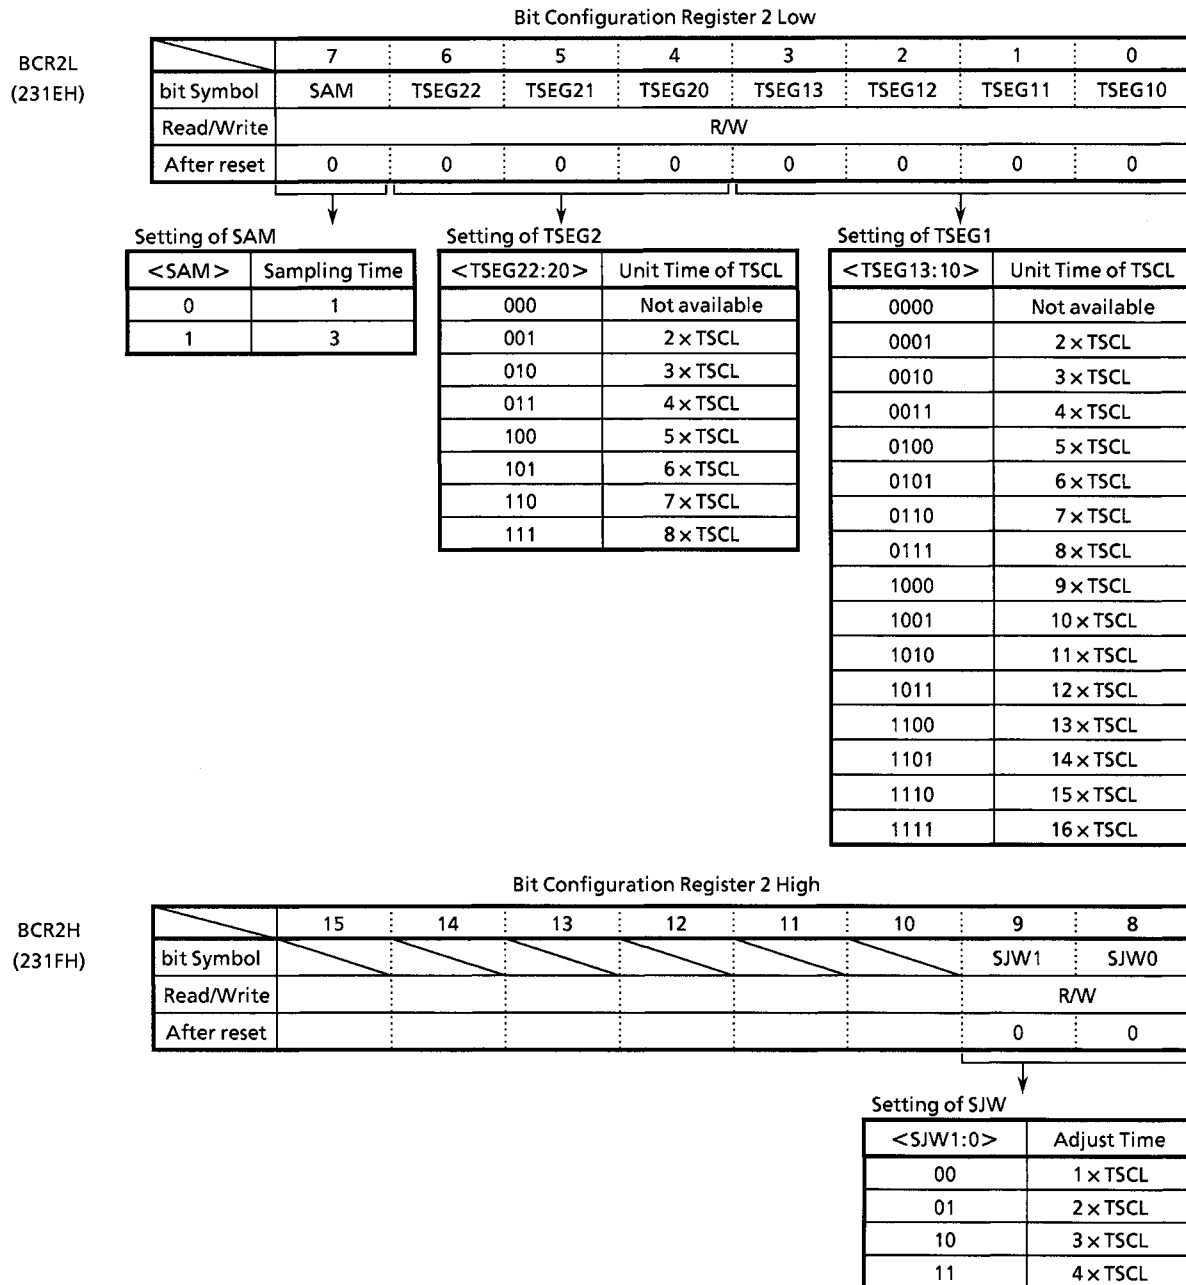

BCR1L (231CH)		7	6	5	4	3	2	1	0
	bit Symbol	BRP7	BRP6	BRP5	BRP4	BRP3	BRP2	BRP1	BRP0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

<BRP7:0> is the baud rate prescaler value. It can be set in the range of 0 to 255.

Bit Configuration Register 1 High

BCR1H (231DH)								
	15	14	13	12	11	10	9	8
	bit Symbol							
	Read/Write							
	After reset							

Bit configuration register 2 (BCR2)

The bit length is determined by parameters TSEG1, TSEG2, and BRP. All CAN controllers on the CAN bus must operate at the same baud rate. If individual CAN controllers operate with different frequencies, the baud rate has to be adjusted by the mentioned parameters. In the bit timing logic, the conversion of the parameters to the required bit timing is materialized. The configuration registers BCR1 and BCR2 contain the data regarding bit timing.

Figure 3.11.3 Bit Timing

The length of TSCL is defined by:

$$TSCL = (<BRP7:0> + 1) / f_{SYS} \quad (f_{SYS} = \text{external clock divided by } 2)$$

f_{SYS} is used to the CAN controller system clock frequency (input clock of the CAN controller).

The length of one bit is determined by the equation below:

$$1 \text{ Bit Time} = SYNCSEG + TSEG1 + TSEG2$$

1 bit time is equal to or greater than $10 \times f_{SYS}$

The synchronization segment SYNCSEG has always the length of $\times TSCL$.

The length of TSEG1 should be equal to or greater than the length of TSEG2.

$$TSEG1 \geq TSEG2.$$

The baud rate is defined by:

$$\text{Baud rate} = f_{SYS} \div [(<BRP7:0> + 1) \times ((<TSEG13:10> + 1) + (<TSEG22:20> + 1) + 1)]$$

IPT (information processing time) is the time segment starting with the sample point reserved for processing of the sampled bit level. IPT is equal to 4 f_{SYS} clock cycles.

The parameter SJW (2bit) indicates by how many units of TSCL it is possible to lengthen or to shorten when re-synchronizing. Values between 1 (SJW = 00b) and 4 (SJW = 11b) are adjustable. The bus line is re-synchronized at each falling edge. The maximum length of SJW is equal to the length of TSEG2.

$$SJW \leq TSEG2$$

With the corresponding bit timing, it is possible to reach a multiple sampling of the bus line at the sample point by setting <SAM> bit. The level determined by the CAN bus then corresponds to the result from the majority decision of the last three values. The three-time sampling is not allowed for $<BRP7:0> < 4$. For $<BRP7:0> < 4$ a one-time sampling will always be performed regardless of the value of <SAM> bit.

Restrictions are as follows:

<BRP7:0>	TSCL length (CAN clock cycles: f_{sys})	IPT length (CAN clock cycles: f_{sys})	TSEG2 minimum length (TSCL)
0	1	4	4
1	2	4	2
>1	<BPR7:0>+1	4	2

Example for setting baud rate

External clock = 24MHz

Internal system clock fsys=12MHz

CAN input clock = fsys

 $1\text{TSCL} = (<\text{BRP7:0}> + 1) \div \text{fsys}$

(1) 1Mbps

<BRP7:0>	TSCL	<TSEG13:10>	<TSEG22:20>	Sample Point(%)

		0101b (6TSCL)	100b (5TSCL)	58.3
0Bh	8	0100b (5TSCL)	001b (2TSCL)	75.0
		0011b (4TSCL)	010b (3TSCL)	62.5
0Fh	6	0010b (3TSCL)	001b (2TSCL)	66.7

Example:

A transmission rate of 1 Mbps will be adjusted, i.e. a bit has a length of 1 μ s. The CAN input clock frequency f_{SYS} is 12 MHz. The baud rate prescaler is set to 0. That means a bit for this data transmission rate has to be programmed with a length of $12 \times TSCL$.

E.g. $\langle BRP7:0 \rangle = 00H$

$\langle TSEG13:10 \rangle = 0101B (6 \times TSCL)$

$\langle TSEG22:20 \rangle = 100B (5 \times TSCL)$

With this setting a threefold sampling of the bus is not possible ($\langle BRP7:0 \rangle < 4$), thus $SAM = 0$ should be set. SJW is not allowed to be greater than $TSEG2$, so the maximum value could be set to $\langle SJW1:0 \rangle = 11B (4 \times TSCL)$

Time stamp feature

There is a free-running 16-bit time stamp counter TSC implemented in the CAN controller to get an indication of the time of reception or transmission of messages. The content of the TSC is written into the time stamp value TSV of the corresponding mailbox when a received message has been stored or a message has been transmitted.

The TSC is driven from the bit clock of the CAN bus line. When the CAN controller is in configuration mode or sleep mode, the TSC will be stopped. After a reset, the TSC can be cleared by writing a value to the time stamp counter prescaler TSP. The TSC can be written and read by CPU in configuration mode and in normal operation mode.

Time stamp counter register (TSC)

		Time Stamp Counter Register Low							
TSCL (2332H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	TSC7	TSC6	TSC5	TSC4	TSC3	TSC2	TSC1	TSC0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

		Time Stamp Counter Register High							
TSCH (2333H) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	TSC15	TSC14	TSC13	TSC12	TSC11	TSC10	TSC9	TSC8
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Overflow of the TSC can be detected by the time stamp counter overflow flag $\langle TSO \rangle$ of the global status register GSR and the time stamp counter overflow interrupt flag $\langle TSOIF \rangle$ of the global interrupt flag register GIF. Both flags are cleared by writing a "1" to the corresponding bit location in GIF.

There is a 4-bit prescaler for the TSC. It is the time stamp counter prescaler register TSP that stores the value to be reloaded into this prescaler. After reset, the TSP register is set to 0, so a value 0 is loaded into the prescaler. The TSC counter's count-up period, TTSC, is shown below:

$$TTSC = TBIT \times (\langle TSP3:0 \rangle + 1) \quad (TBIT: \text{bit cycle})$$

(7) Status registers

Global status register (GSR)

Global Status Register Low								
GSRL (231AH)	7	6	5	4	3	2	1	0
	bit Symbol	CCE	SMA	HMA	TSO	BO	EP	EW
	Read/Write	R			R			
	After reset	1	0	0	0	0	0	0

Global Status Register High								
GSRH (231BH)	15	14	13	12	11	10	9	8
	MsgInSlot <3:0>				RM	TM		
	R							
	After reset	1	1	1	1	0	0	

MsgInSlot: Message In Slot

Indicates a message in the transmission slot.

0000: Message of mailbox 0

0001: Message of mailbox 1

:

1110: Message of mailbox 14

1111: No transmission message

RM: Receive Mode

0: The CAN controller is not receiving a message.

1: The CAN controller is receiving a message. That means the CAN controller is not the transmitter of the message and the bus is not idle.

TM: Transmit Mode

0: The CAN controller is not transmitting a message.

1: The CAN controller is transmitting a message. That means the CAN controller stays transmitter until the bus is idle or it loses arbitration.

CCE: Change Configuration Enable

0: The CAN controller is not in the configuration mode. (Normal operation)

1: The CAN controller has entered the configuration mode.

SMA: Sleep Mode Acknowledge

0: The CAN controller is not in the sleep mode. (Normal operation)

1: The CAN controller has entered the sleep mode.

HMA: Halt Mode Acknowledge

0: The CAN controller is not in the halt mode. (Normal operation)

1: The CAN controller has entered the halt mode.

TSO: Time Stamp Overflow Flag

0: There was no overflow of the time stamp counter.

1: There was at least one overflow of the time stamp counter since this bit has been cleared.

To clear this bit, clear the <TSOIF> bit in the GIF register.

BO: Bus-Off Status

- 0: The CAN controller is in the bus-on status. (Normal operation)
- 1: The CAN controller is in the bus-off status.
There is an abnormal rate of occurrences of errors on the CAN bus. This condition occurs when the transmit error counter TEC has reached the limit of 256. During bus-off no messages can be received or transmitted. The CAN controller will go to bus-on automatically after the bus-off recovery sequence. After entering bus-off, the error counters are undefined.

EP: Error Passive Status

- 0: The CAN controller is in the error active mode.
The values of both transmit error counter TEC and receive error counter REC are less than 128.
- 1: The CAN controller is in the error passive mode.
Either one of or both the transmit error counter TEC and receive error counter REC have reached the error passive status of 128.

EW: Warning Status

- 0: Both values of the error counters TEC and REC are less than or equal to 96.
- 1: At least one of the error counters is greater than 96 and reached the warning level.

CAN error counter register (CEC)

		CAN Error Counter Register Low							
CECL (232EH) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	REC7	REC6	REC5	REC4	REC3	REC2	REC1	REC0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

		CAN Error Counter Register High							
CECH (232FH) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	TEC7	TEC6	TEC5	TEC4	TEC3	TEC2	TEC1	TEC0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

The CAN controller contains two error counters: receive error counter REC and transmit error counter TEC. The values of both counters can be read by the CPU. A write access to the error counters is only possible in the test error mode, at the same time as and with the same value of the lower 8bit (<TSTERR> bit in MCR register is set). These error counters are incremented or decremented according to the CAN version 2.0B.

The controller enters the following three states depending on the values of REC and TEC.

- (1) Error active state ($TEC < 128$ and $REC < 128$)

The state where an error rarely occurs.

The CAN controller is in an error active state after reset release.

When an error is detected, an active error flag is transmitted.

- (2) Error passive state ($TEC \geq 128$ or $REC \geq 128$)

The state where many errors have occurred.

When an error is detected, a passive error flag is transmitted.

- (3) Bus-off state ($TEC \geq 256$)

The CAN controller cannot perform message transmission to and reception from the CAN bus.

Receive error counter REC is not incremented after exceeding the error passive limit (128). After the correct reception of a message when $REC = 128$, the counter is set to a value between 119 and 127. After reaching the bus-off status, the counts are undefined.

A CAN controller which is in bus-off state will automatically enter error active state if 11 continuous recessive bits are detected 128 times on the CAN bus.

All internal flags are reset, and the error counters are cleared. The configuration registers keep the programmed values. The values of the error counters are undefined during bus-off status.

When the CAN controller enters configuration mode (see 3.11.4 (1) Configuration mode), the error counters will be cleared.

(8) Interrupt control registers

The CAN controller has the following interrupt sources:

- Transmit interrupt
When a message has been transmitted successfully
- Receive interrupt
When a message has been received successfully
- Remote frame pending interrupt
When a remote frame is received
- Wake-up interrupt
When the CAN controller is awakened from sleep mode
- Receive message lost interrupt
When a receive message is lost
- Time stamp counter overflow interrupt
When the time stamp counter has overflowed
- Bus off interrupt
When the CAN controller enters the bus-off mode
- Error passive interrupt
When the CAN controller enters the error passive mode
- Warning level interrupt
When at least one of the two error counters is greater than 96 and has reached the warning level.

These interrupt sources are divided into three groups:

- Receive interrupt (INTCR)
- Transmit interrupt (INTCT)
- Global interrupt (INTCG)

There is one interrupt output line for each group. INTCR is dedicated to receive interrupts, INTCT is dedicated to transmit interrupts and INTCG to the global interrupts.

Global interrupt flag register (GIF)

Global Interrupt Flag Register Low								
	7	6	5	4	3	2	1	0
GIFL (2320H)	RFPF	WUIF	RMLIF	—	TSOIF	BOIF	EPIF	WLIF
bit Symbol								
Read/Write	R/C							
After reset	0	0	0	—	0	0	0	0

Global Interrupt Flag Register High								
	15	14	13	12	11	10	9	8
GIFH (2321H)								
bit Symbol								
Read/Write								
After reset								

The interrupt flag bits will be set if the corresponding interrupt condition has occurred. If the corresponding interrupt mask bit is set in the GIM register, an interrupt pulse on the global interrupt line INTCG will be generated. As long as an interrupt flag in the GIF register is set, if the corresponding interrupt source generates a new interrupt event, a new interrupt pulse on INTCG will not be generated. If an interrupt flag in the GIF register is set and another interrupt source generates an interrupt event, then a new interrupt pulse on INTCG will be generated.

If one or more interrupt flags have been cleared and one or more interrupt flags are still set, a new global interrupt pulse INTCG will be generated.

The interrupt flags will be cleared by writing a “1” to the corresponding bit location.

RFPF: Remote Frame Pending Flag

- 0: No remote frame has been received.
- 1: A remote frame has been received (in a receive-mailbox).

This bit will not be set if the identifier of the remote frame matches to a transmit-mailbox with <RFH> set.

WUIF: Wake-Up Interrupt Flag

- 0: The CAN controller is in the sleep mode or the normal operation mode.
- 1: The CAN controller has left the sleep mode.

RMLIF: Receive Message Lost Interrupt Flag

- 0: No receive message has been lost.
- 1: For at least one of the receive-mailboxes, a receive message has been lost.
At least one of the bits in the RML register is set.

TSOIF: Time Stamp Counter Overflow Interrupt Flag

- 0: There have been no overflows of the time stamp counter since this bit has been cleared.
- 1: There was at least one overflow of the time stamp counter since this bit has been cleared.

BOIF: Bus-Off Interrupt Flag

- 0: The CAN controller is still in the bus-on mode.
- 1: The CAN controller has entered the bus-off mode.

EPIF: Error Passive Interrupt Flag

- 0: The CAN controller is still in error active mode.
- 1: The CAN controller has entered the error passive mode.

WLIF: Warning Level Interrupt Flag

- 0: None of the error counters has reached the warning level.
- 1: At least one of the error counters has reached the warning level.

Global interrupt mask register (GIM)

		Global Interrupt Mask Register Low							
GIML (2322H)		7	6	5	4	3	2	1	0
	bit Symbol	RFPM	WUIM	RMLIM	—	TSOIM	BOIM	EPIM	WLIM
	Read/Write	R/W							
	After reset	0	0	0	— Note)	0	0	0	0

		Global Interrupt Mask Register High							
GIMH (2323H)		15	14	13	12	11	10	9	8
	bit Symbol								
	Read/Write								
	After reset								

Note: Write to 0

Each interrupt flag bit in the GIF register is masked by the corresponding mask bit in the GIM register.

If a bit in the GIM register is 0, the interrupt generation for the corresponding global interrupt event is disabled, and if it is 1, the interrupt generation is enabled. After reset, all bits in the GIM register are cleared, thereby disabling global interrupt.

Mailbox interrupts

Separate interrupt outputs are provided for mailbox interrupts independently of global interrupts. These include mailbox transmit interrupt INTCT, and mailbox receive interrupt INTCR, that depend on mailbox settings. A mailbox transmit interrupt flag register MBTIF is provided for mailbox transmit interrupts, and a mailbox receive interrupt flag register MBRIF is provided for mailbox receive interrupts.

In addition, there is a mailbox interrupt mask register MBIM that enables or disables each mailbox interrupt.

Mailbox interrupt mask register (MBIM)

Mailbox Interrupt Mask Register Low									
MBIML (2328H)		7	6	5	4	3	2	1	0
	bit Symbol	MBIM7	MBIM6	MBIM5	MBIM4	MBIM3	MBIM2	MBIM1	MBIM0
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Mailbox Interrupt Mask Register High									
MBIMH (2329H)		15	14	13	12	11	10	9	8
	bit Symbol	MBIM15	MBIM14	MBIM13	MBIM12	MBIM11	MBIM10	MBIM9	MBIM8
	Read/Write	R/W							
	After reset	0	0	0	0	0	0	0	0

Each bit corresponds to mailboxes 0 through 15.

The MBIM register settings determine whether to enable or disable each mailbox interrupt.

If a bit in the MBIM register is 0, the interrupt generation for the corresponding mailbox is disabled.

If a bit in the MBIM register is 1, the interrupt generation for the corresponding mailbox is enabled.

Mailbox transmit interrupt flag register (MBTIF)

Mailbox Transmit Interrupt Flag Register Low									
MBTIFL (2324H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	MBTIF7	MBTIF6	MBTIF5	MBTIF4	MBTIF3	MBTIF2	MBTIF1	MBTIF0
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Mailbox Transmit Interrupt Flag Register High									
MBTIFH (2325H) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol		MBTIF14	MBTIF13	MBTIF12	MBTIF11	MBTIF10	MBTIF9	MBTIF8
	Read/Write		R/C						
	After reset		0	0	0	0	0	0	0

This register is provided for mailbox transmit interrupts. Each bit in this register corresponds to mailboxes 0 through 15. The interrupt flag for mailbox 15, the <MBTIF15> flag, is nonexistent because mailbox 15 is the receive-only mailbox. If mailbox “n” is set for receive, the corresponding interrupt flag in this register, the <MBTIFn> flag, will always be read as 0.

If a message in mailbox “n” has been transmitted successfully and the mask bit <MBIMn> is set to 1, the corresponding transmit interrupt flag <MBTIFn> will be set. If no other bit was set before in the MBTIF register, transmit interrupt pulse INTCT will be generated.

If, for any mailbox, the mask bit in the MBIM register is 0, the transmit interrupt flag in the MBTIF register will not be set and no transmit interrupt pulse INTCT will be generated. Information about a successful transmission can be read from the TA register.

If one or more transmit interrupt flags have been set in the MBTIF register and another interrupt condition has occurred, no interrupt will be generated, but the corresponding flag in the MBTIF register will be set.

If there one or more transmit interrupt flags are set after clearing one or more transmit interrupt flags, another mailbox transmit interrupt pulse INTCT will be generated.

The interrupt flags in the MBTIF register will be cleared by writing a 1 from the CPU to the MBTIF register. Writing a 0 has no effect. The corresponding status flags in the TA register must be cleared separately.

Note that interrupt flags in the MBTIF register must be confirmed as 1 (active), before clearing.

Mailbox receive interrupt flag register (MBRIF)

Mailbox Receive Interrupt Flag Register Low									
MBRIFL (2326H) RMW instructions prohibited		7	6	5	4	3	2	1	0
	bit Symbol	MBRIF7	MBRIF6	MBRIF5	MBRIF4	MBRIF3	MBRIF2	MBRIF1	MBRIF0
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

Mailbox Receive Interrupt Flag Register High									
MBRIFH (2327H) RMW instructions prohibited		15	14	13	12	11	10	9	8
	bit Symbol	MBRIF15	MBRIF14	MBRIF13	MBRIF12	MBRIF11	MBRIF10	MBRIF9	MBRIF8
	Read/Write	R/C							
	After reset	0	0	0	0	0	0	0	0

This register is provided for mailbox receive interrupts. Each bit in this register corresponds to mailboxes 0 through 15. If mailbox “n” is set for transmit, the corresponding interrupt flag in this register, the <MBRIFn> flag, will always be read as 0.

If a message in mailbox “n” has been received successfully and the mask bit <MBIMn> is set to 1, the corresponding receive interrupt flag <MBRIFn> will be set. If no other bit was set before in MBRIF register, receive interrupt pulse INTCR will be generated.

If for a mailbox the mask bit in MBIM register is 0, the receive interrupt flag in MBRIF register will not be set and no receive interrupt pulse INTCR will be generated. The information about a successful reception could be read from the RMP register respectively.

If one or more receive interrupt flags have been set in MBRIF register and another interrupt condition has been occurred, no interrupt will be generated, but the corresponding flag in MBRIF register will be set.

If there is one or more receive interrupt flags set after clearing one or more receive interrupt flags, another mailbox receive interrupt pulse INTCR will be generated.

The interrupt flags in MBRIF register will be cleared by writing a 1 from the CPU to MBRIF register. Writing a 0 has no effect. The corresponding status flags in RMP register have to be cleared separately.

Note that interrupt flags in the MBRIF register must be confirmed as 1 (active), before clearing.

3.11.4 Description of Mode

(1) Configuration mode

The CAN controller must be initialized (set the bit configuration registers BCR1 and BDR2) before activation. The BCR1 and BCR2 registers can only be modified when the module is in the configuration mode. After reset, the configuration mode is active and the <CCR> bit of the MCR register and the <CCE> bit of the GSR register are set to 1. The CAN controller can be set to the normal operation mode by writing a 0 to the <CCR> bit. After leaving the configuration mode, the <CCE> bit will be set to 0 and the power-up sequence will start. The power-up sequence consists of detecting eleven consecutive recessive bits on the CAN bus line. After the power-up sequence, the CAN controller is bus-on and ready for operation.

When the <CCR> bit is set to 1, the CAN controller will enter the configuration mode from the normal operation mode. After the CAN controller has entered the configuration mode, the <CCE> bit will be set to 1. See also the flowchart in Figure 3.11.5 (Flowchart of CAN Initialization). On entering the configuration mode, the error counter CEC, the time stamp counter TSC and the time stamp hold register will be cleared.

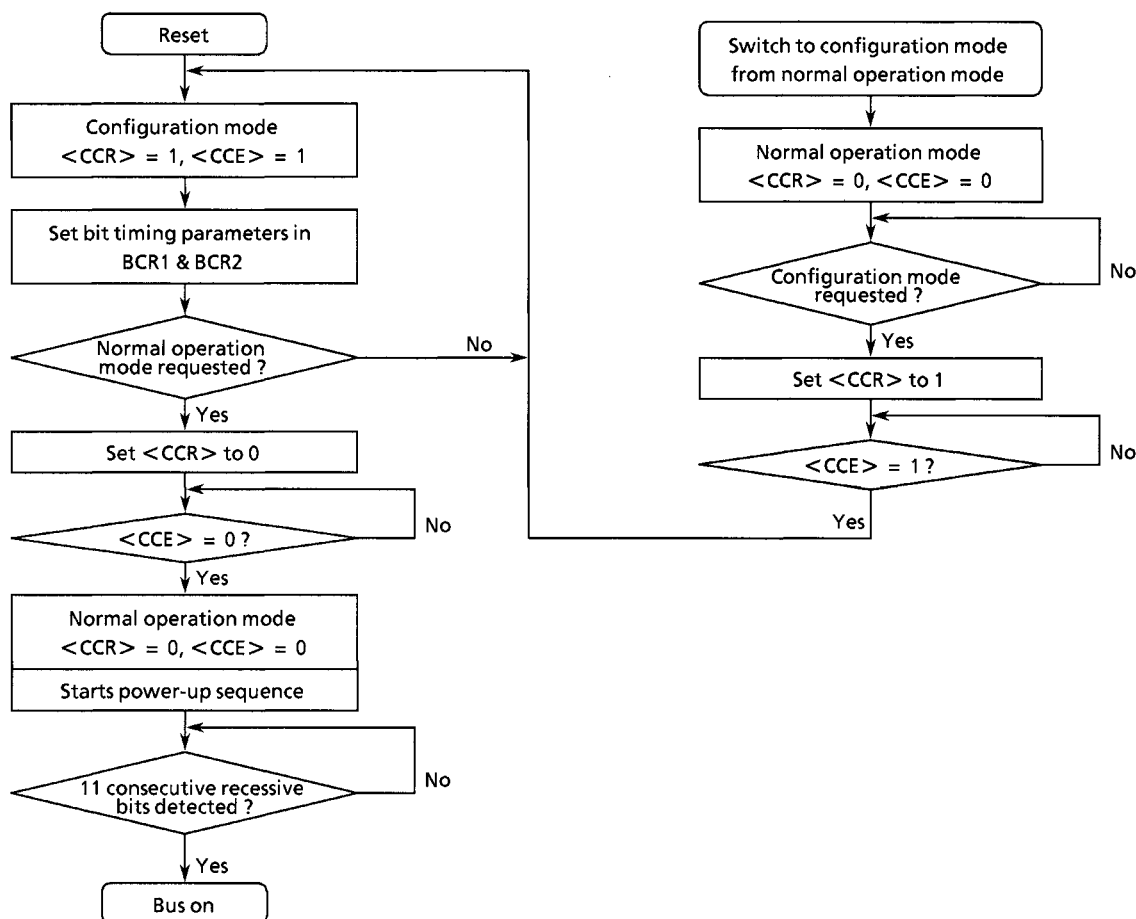

Figure3.11.5 Flowchart of CAN Initialization

(2) Sleep mode

The sleep mode will be requested by writing 1 to the <SMR> bit of the MCR register. When the CAN controller enters the sleep mode, the status bit <SMA> of the GSR register will be set to 1.

During the sleep mode, the clock of the CAN controller is switched off. Only the wake up logic will be active. The read value of the GSR register will be F040H, this means there is no message in transmit buffer and the sleep mode is active (the <SMA> bit is set to 1). Read accesses to all other registers will deliver the value 0000H. Write accesses to all registers other than the MCR register will be denied.

The CAN controller leaves the sleep mode if a write access to the MCR register has been detected or there is any bus activity detected on the CAN bus line (with <WUBA> = 1). The CAN controller then begins its power-up sequence. The CAN controller waits until detecting 11 consecutive recessive bits on the RX input line and goes to bus active after them. The first message that initiates the bus activity cannot be received.

In sleep mode, the CAN error counters and all transmission request set bits <TRSn> will be cleared. After leaving the sleep mode, the <SMR> bit in the MCR register and the <SMA> bit in the GSR register will be cleared.

If the CAN controller is transmitting a message when the <SMR> bit is set, the CAN controller will not switch to the sleep mode immediately. It will continue until a successful transmission or after losing arbitration, or until a successful reception or an error condition occurs on the CAN bus line. By this means, the CAN controller will initiate no error condition on the CAN bus line.

(3) Halt mode

The halt mode will be requested by writing 1 to the <HMR> bit of the MCR register. When the CAN controller enters the halt mode, the <HMA> bit of the GSR register will be set. During the halt mode the CAN controller does not send or receive any messages. The CAN controller is still active on the CAN bus line. Error Flags and Acknowledge Flags will be sent. The CAN controller leaves the halt mode if the <HMR> bit is reset to 0.

If the CAN controller is transmitting a message when the <HMR> bit is set, the transmission will continue until successful, or until a lost arbitration is detected. By this means the CAN controller will initiate no error condition on the CAN bus line.

(4) Test loopback mode

In this mode, the CAN controller can receive its own transmitted message and will generate its own acknowledge bit. No other CAN controller is necessary for this operation. The only supposition is that the RX and TX lines must be connected to a CAN bus transceiver or directly together.

In the test loopback mode, the CAN controller can transmit a message from one mailbox and receive it in another mailbox. The set-up for the mailboxes is the same as in the normal operation mode.

The test loopback mode can only be enabled or disabled in the configuration mode. Figure 3.11.6 shows the flowchart of the test loopback mode and the test error mode set-up.

(5) Test error mode

The error counters can only be written when the CAN controller is in the test error mode.

When the CAN controller is in the test error mode, both error counters will be written at the same time with the same value (lower 8 bits). The maximum value that can be written into the error counters is 255. Thus, the error counter value of 256 which forces the CAN controller into the bus-off mode can not be written into the error counters.

The test error mode can only be enabled or disabled in the configuration mode. Figure 3.11.6 shows the flowchart of the test loopback mode and the test error mode set-up.

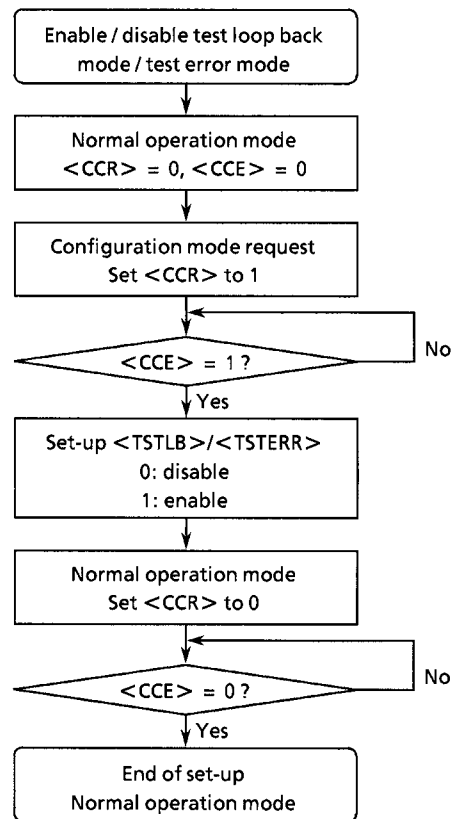

Figure3.11.6 Flowchart of the test loopback mode/ test error mode set-up

3.11.5 Functional Description

(1) Transmit mode

Figure 3.11.7 shows the flowchart of message transmit using the transmit interrupt INTCT.

It is also possible to use polling instead of interrupt. In this case, “Transmit interrupt generated?” is replaced by “<TAn> = 1?”. “Set <MBIMn> to 1” and “Clear <MBTIFn>” must be removed from the flow.

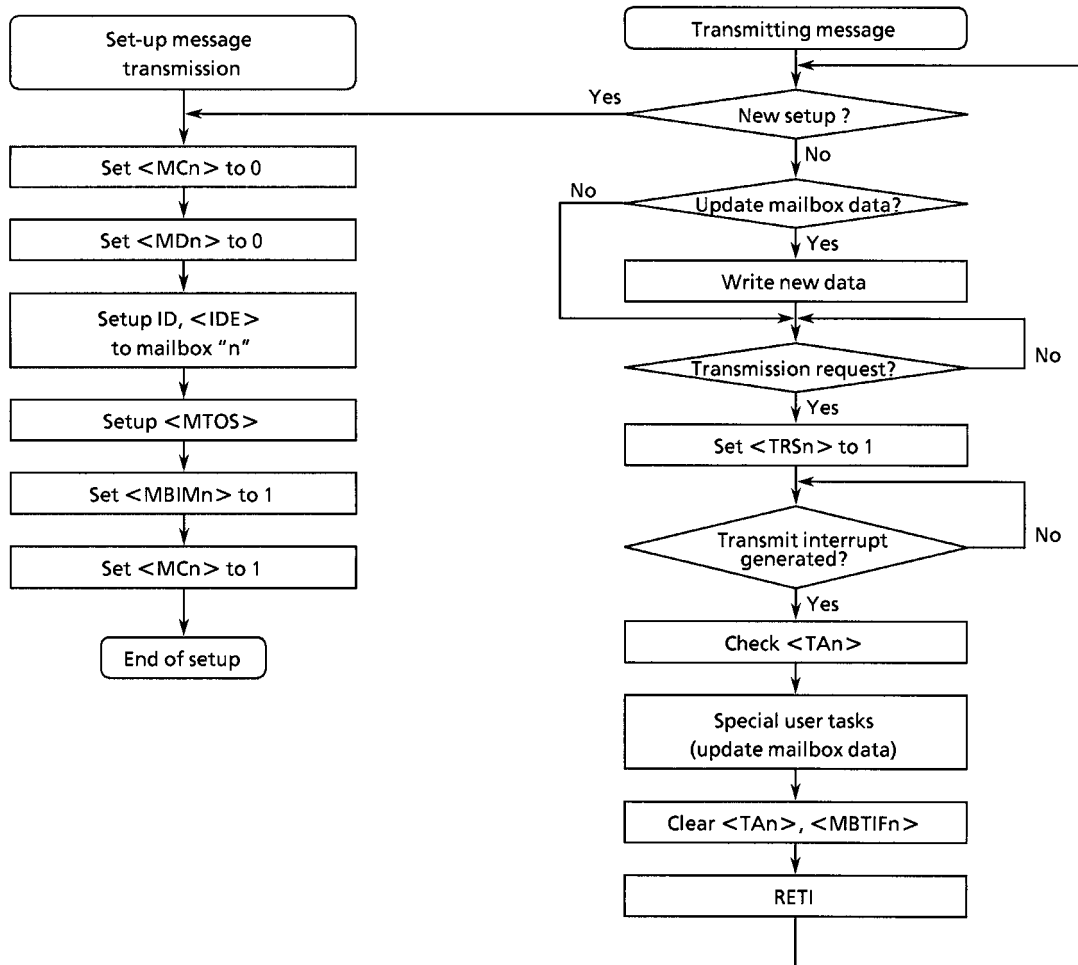

Figure 3.11.7 Flowchart of message transmission

(2) Receive mode

If the CAN controller has received a message from the CAN bus line, this message will be located in the receive buffer. The identifier of the message stored in the receive buffer will be compared to the identifier of the mailbox. If <GAME>/<LAME> bit is set, the global/local acceptance mask register GAM/LAM will be used. If there is one of the following conditions found, no further compare will be performed.

- Data frame and a matching identifier in a mailbox configured as receive
- Remote frame and a matching identifier in a mailbox configured as receive
- Remote frame and a matching identifier in a mailbox configured as transmit and <RFH> bit is set

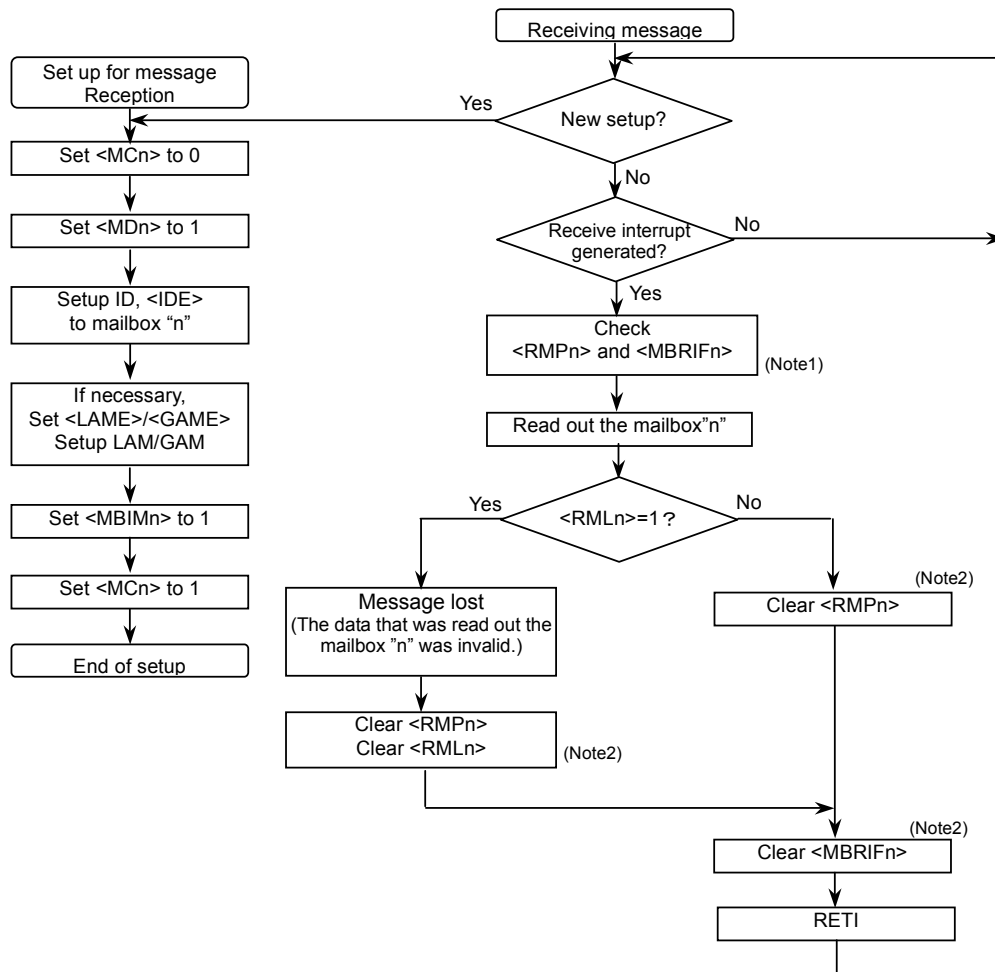

The minimal time to save a next received message after the <RMP> bit set depends on the configured bit timing. In the case of the data length code = 0, the minimal time is as follows.

- Standard format: 47 bit times - 16 f_{SYS}
- Extended format: 67 bit times - 16 f_{SYS}

[1] Data frames

Figure 3.11.8 shows one example of the flowchart of message reception using the receive interrupt INTCR.

It is also possible to use polling instead of the interrupt. In this case, “Receive interrupt generated?” is replaced by “<RMPn> = 1?”. “Set <MBIMn> to 1” and “Clear <MBRIFn>” must be removed from the flow.

Note1: Be sure to check <RMPn> and <MBRIFn>

Note2: If “Clear <RMPn>” is executed, and mailbox “n” receives a message before “Clear <MBRIFn>” is also executed, then it is possible that <RMPn> will be set at 1 (<MBRIFn>=0).

Figure 3.11.8 Flowchart of message reception (example)

[2] Remote frame

Figure 3.11.9 shows the flowchart of one example of the handling of remote frames by using the automatic reply feature. This feature is available when the <RFH> bit of a mailbox configured for transmission is set. To avoid data inconsistency problems when updating the mailbox data, the CDR register is used.

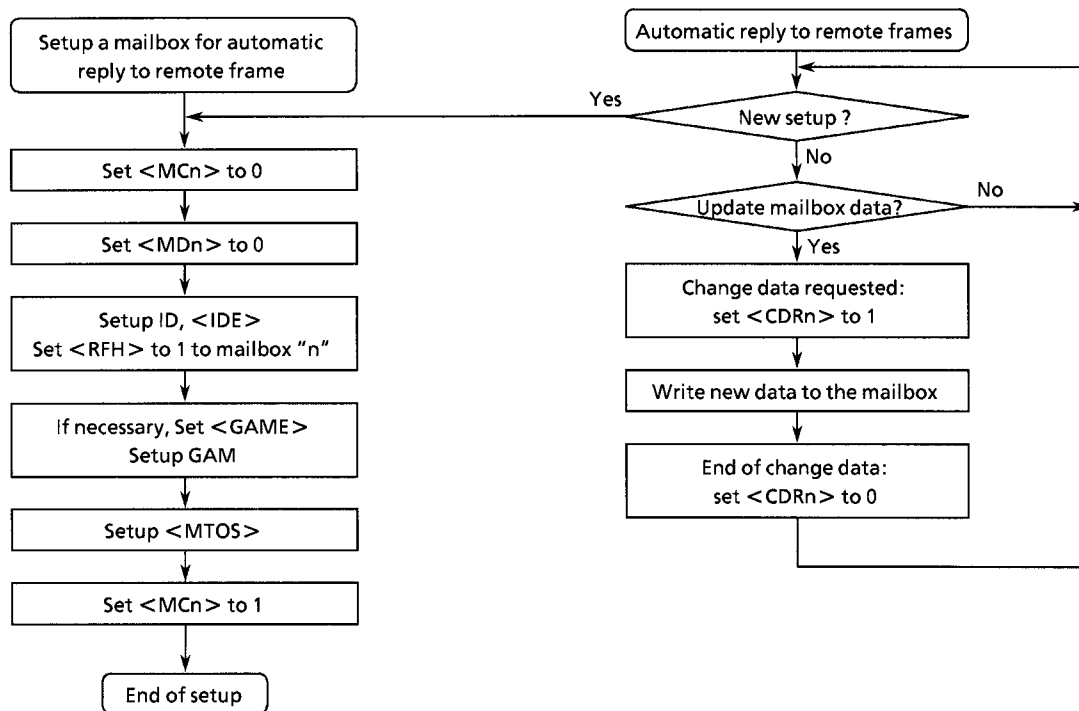

Figure 3.11.9 Flowchart of remote frame handling with the automatic reply feature (example)

3.12 Serial Expansion Interface (SEI)

3.12.1 Overview

The SEI is one of the serial interfaces built into the TMP95CU54A, which can be connected to peripheral devices, by full duplex synchronous communication protocol. The TMP95CU54A incorporates one channel of this serial expansion interface.

The SEI can also support the Micro DMA mode corresponding to the micro DMA transfer.

(1) Features

- The master outputs the shift clock only during data transfer
- The clock polarity and phase are programmable
- The data are 8 bits long
- Either MSB first or LSB first can be selected
- Micro DMA mode support for micro DMA transfers
- Transfer rate: 4 Mbps, 2 Mbps, 1 Mbps or 250 kbps (when operating at 24 MHz)
- Error detection function

[1] Write collision detection: when writing to the shift register during data transfer

[2] Overflow detection: when receiving new data while the transfer end flag is set (slave only)

Note: There is no Mode fault detection function. Set P6FC<P60F> which is the enable / disable bit for Mode fault detection to "1", and disable the Mode fault detection function.

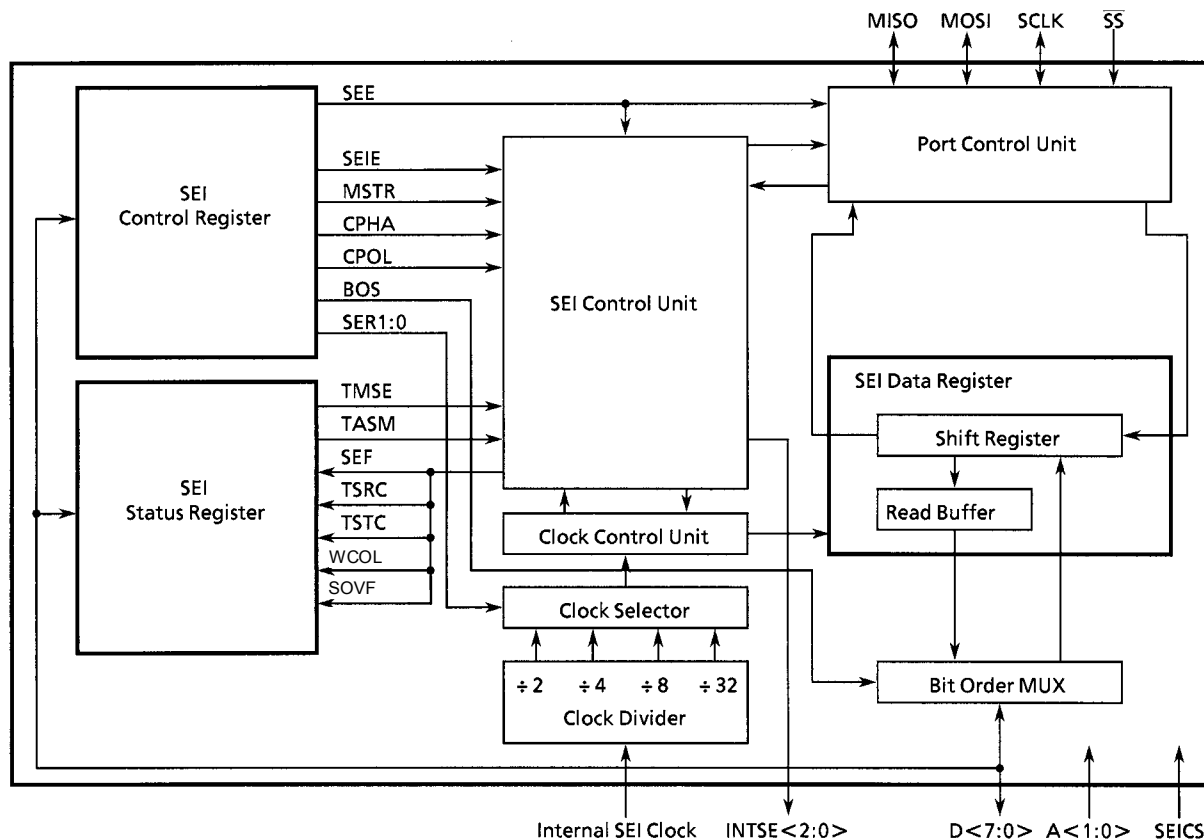

Figure 3.12.1 SEI Block Diagram

3.12.2 SEI Operation

During a SEI transfer, data is simultaneously transmitted (shifted out serially) and received serially (shifted in serially). The SEI clock (SECLK) takes synchronously the two serial data lines (MOSI/MISO) in order to shift and sample information on the lines. A slave selection line (\overline{SS}) selects slave devices individually. A slave device not selected cannot use the SEI bus.

(1) SEI clock phase and polarity controls

Software can select any four combinations of serial clock phase and polarity using two bits in the SEI control register (SECR). The clock polarity is set by the <CPOL> bit, and the clock is either active "H" or active "L". The clock phase <CPHA> control bit selects one of two fundamentally different transfer formats. The clock phase and polarity should be identical for the master SEI device and the communicating slave device.

(2) SEI data and clock timing

The SEI programmable clock timing and data can be connected to almost any synchronous serial device. Please see "3.12.4 SEI transfer format" for a detailed description of the transfer format.

3.12.3 SEI Signal Lines

There are four input/output pin signals associated with the SEI transfer. Every signal depends on the mode (master/slave) of the SEI device.

(1) SCLK

The SCLK pin functions as an output pin when the SEI is set for master, and functions as an input pin when the SEI is set for slave.

When the SEI is set for master, the SCLK signal is supplied by the internal SEI clock generation circuit. When the master starts transferring data, eight clock cycles are automatically output at the SCLK pin. When the SEI is set for slave, the SCLK pin functions as an input pin, in which case the SCLK signal from the master synchronizes data transfers between the master and slave. The slave device ignores the SCLK signal if the slave select \overline{SS} pin is high.

In both master and slave SEI devices, data is shifted in or out at each rising or falling edge of the SCLK signal and is sampled at the opposite edge where the data is stable. Edge polarity is determined by the SEI transfer protocol.

(2) MISO/MOSI

The MISO and MOSI pins are used for transmitting and receiving serial data.

When the SEI is configured as a master, MISO is the data input line and MOSI is the data output line.

When the SEI is configured as a slave, these pins reverse roles.

All SCLK pins are connected together, as are all MOSI pins and all MISO pins. Refer to "Figure 3.12.5 Configuration of SEI system". A single SEI device is configured as a master, while all other SEI devices on the SEI bus are configured as slaves. The single master drives the transfer clock and data out of its SCLK and MOSI pins to the SCLK and MOSI pins of the slaves. One selected slave device optionally drives data out of its MISO pin to the MISO master pin.

The SCLK, MISO and MOSI pins can be set up to function as programmable open-drain pins.

(3) \overline{SS}

The \overline{SS} pin is used to enable the SEI slave for transfer and receive. If the \overline{SS} pin of a slave is inactive (high), the device ignores SCLK clocks and keeps the MISO output pin in the high-impedance state.

3.12.4 SEI Transfer Format

The transfer format is determined by the setting of the <CPHA> bit and the <CPOL> bit in the SECR register. The <CPHA> bit switches between two different transfer protocols.

(1) Transfer Format of <CPHA> = 0

Figure 3.12.2 shows the transfer format for a <CPHA>=0 transfer.

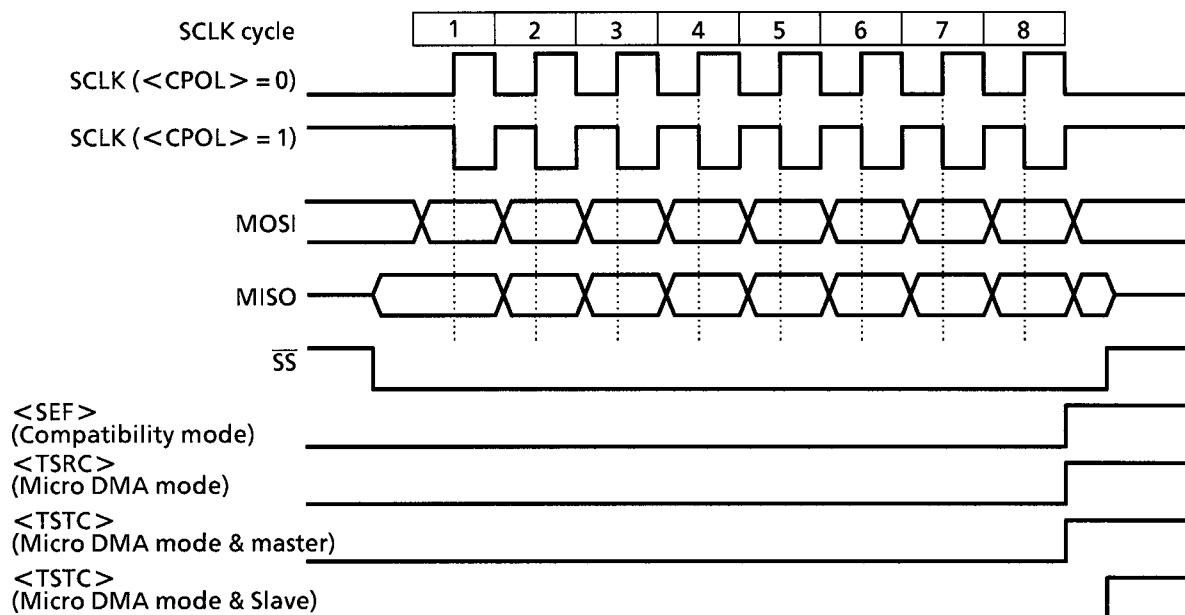

Figure 3.12.2 Transfer format of <CPHA>=0

In this transfer format, the first bit is sampled in on the first clock edge. This will be on a rising edge when <CPOL> = 0 and on a falling edge when <CPOL> = 1. With <CPOL> = 0 the shift clock will idle low, with <CPOL> = 1 it will idle high.

In master mode, when a transfer is initiated by writing new data to the SEDR register, the new data is placed on the MOSI pin for half a clock cycle before the shift clock starts to operate. The <BOS> bit in the SECR register determines whether the data will be shifted out in a MSB or LSB order. After the last shift cycle, the <SEF> flag (in Compatibility mode) or the <TSRC> flag and <TSTC> flags (in Micro DMA mode) will be asserted.

In slave mode, the SEDR register is not allowed to be written if the \overline{SS} signal is low. A write attempt in this state will result in a write collision and the <WCOL> bit will be asserted in the SESR register. Therefore, even if the transfer has been completed and the <SEF> flag or <TSRC> flag bit has been asserted, software has to wait until the \overline{SS} signal goes high again before writing new data to the SEDR register. To allow the use of a micro DMA to transfer data to the SEDR register in slave mode, the <TSTC> flag is delayed until \overline{SS} goes high.

(2) Transfer format of $\langle \text{CPHA} \rangle = 1$

Figure 3.12.3 shows the transfer format for a $\langle \text{CPHA} \rangle = 1$ transfer.

Figure 3.12.3 Transfer format of $\langle \text{CPHA} \rangle = 1$

In this transfer format, the first bit is sampled in on the second clock edge. This will be on a falling edge when $\langle \text{CPOL} \rangle = 0$ and on a rising edge when $\langle \text{CPOL} \rangle = 1$. If $\langle \text{CPOL} \rangle = 0$, the shift clock is a rising edge; with $\langle \text{CPOL} \rangle = 1$ it is a falling edge.

In master mode, when a transfer is initiated by writing new data to the SEDR register, the data is placed on the MOSI pin with the first edge of the shift clock. Again, the first bit to be transferred will be determined by the $\langle \text{BOS} \rangle$ bit in the SECR register.

Unlike in the $\langle \text{CPHA} \rangle = 0$ format, the SEDR register is allowed to be written in slave mode even if the $\overline{\text{SS}}$ signal is low.

In both master and slave mode, the $\langle \text{SEF} \rangle$ flag (in Compatibility mode) or the $\langle \text{TSRC} \rangle$ flag and $\langle \text{TSTC} \rangle$ flag (in Micro DMA mode) will be asserted simultaneously after the completion of the last shift cycle. An attempt to write the SEDR register while the data shifting is still in progress will result in a write collision.

3.12.5 Functional Description

Figure 3.12.4 shows master-to-slave connection via the SEI.

The different nodes on a SEI bus function like a distributed shift register. When data is sent from the MOSI pin of the master device to the corresponding pin of the slave device, data from the slave is sent back from the MISO pin of the slave device to the corresponding pin of the master device.

This means that data is communicated in full-duplex mode and data output and data input are synchronized by the same clock signal. After a transfer, the data transmitted from the 8-bit shift register is replaced with receive data.

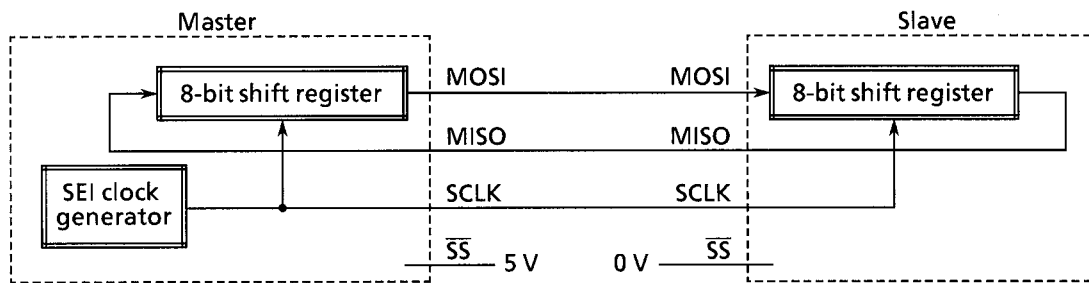

Figure 3.12.4 Connection between Master and Slave in SEI

Figure 3.12.5 shows a configuration of the SEI system.

Port 6, the SEI output, can be set for open-drain output programmable. Therefore, this port can be connected to multiple devices.

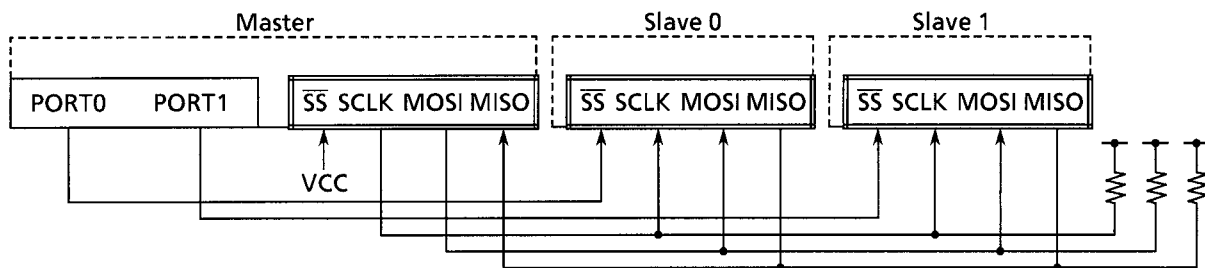

Figure 3.12.5 Configuration of SEI System (comprising one master and two slaves)

3.12.6 Operation Modes

SEI allows the programmer the choice of 2 fundamentally different operation modes - the Compatibility mode and the Micro DMA mode. These operation modes differ in terms of flag clearing, interrupt generation and whether or not - micro DMA is used. The table below shows the differences between the two operation modes.

Table 3.12.1 Differences between the Two Operation Modes

	Compatibility Mode	Micro DMA Mode
Error Flag Clearing	Reading a register with the Status flag set, followed by SECR or SEDR register access	Writing a "1" to the status register
Transfer Status Flag Clearing	Reading a register with the Status flag set, followed by an access to the data register	Writing a "1" to the status register or by reading or writing the data register
Interrupt generation	INTSE0: <SEF>	INTSE0: <WCOL> or <SOVF> INTSE1: <TSRC> INTSE2: <TSTC>
Micro DMA use	No	Yes

SEI can be switched between these operation modes, if SEI is disabled (<SEE> = 0), by setting the <TMSE> bit in the SESR register.

3.12.7 SEI Registers

Use SEI control register SECR, SEI status register SESR and SEI data register SEDR to set SEI.

Note: When accessing the SEI registers, at least 4 states must be inserted between SEI register write and SEI register read. Please remember this when programming.

Example:

```
LD (SEDR), data1 : write SEDR
NOP               : } or other instructions which do not access the SEI registers
NOP               : }
LD A, (SESR)      : read SESR
LD (SESR), data2  : write SESR
NOP               : } or other instructions which do not access the SEI registers
NOP               : }
LD A, (SESR)      : read SESR
```

(1) SEI control register (SECR)

SEI Control Register								
SECR (009DH)	7	6	5	4	3	2	1	0
	bit Symbol	SEIE	SEE	BOS	MSTR	CPOL	CPHA	SER1 SER0
	Read/Write	R/W						
	After reset	0	0	0	0	0	1	0 0
Read- modify-write instructions prohibited.	Function	SEI interrupt 0: Disabled 1: Enabled	SEI operation 0: Stopped 1: Operating	Bit order Select 0: MSB first 1: LSB first	Mode select 0: Slave 1: Master	Clock Polarity select See Fig 3.12.2, 3.12.3	Clock Phase Select See Fig 3.12.2, 3.12.3	SEI transfer rate select See table 3.12.2

<SEIE>: SEI interrupt enable

Compatibility mode:

0: SEI interrupts are disabled.

1: SEI interrupts are enabled. A SEI interrupt is requested if the <SEF> flag is being asserted.

Micro DMA mode:

The <SEIE> bit is obsolete in Micro DMA mode. Only the interrupt controller registers are used to enable or disable interrupts.

<SEE>: SEI function enable

0: SEI function is off. It is necessary to disable the SEI function to switch between the Micro DMA mode and the compatibility mode. Wait until the transfer in progress is completed before you clear the <SEE> bit to stop the SEI operation.

1: SEI function is on. Before using the SEI function, make sure that the port function is set for the SEI function.

<BOS>: Bit order select

The bit order selection bit <BOS> selects whether the data to be transferred is MSB first or LSB first.

0: The MSB bit of the SEDR register (bit 7) will be transmitted first.

1: The LSB bit of the SEDR register (bit 0) will be transmitted first.

<MSTR>: Master/Slave mode select

0: SEI is configured as slave.

1: SEI is configured as master..

<CPOL>: Clock polarity select

0: Active “H” level clock is selected. The SECLK clock is at idle “L” level when not transmitting..

1: Active “L” level clock is selected. The SECLK clock is at idle “H” level when not transmitting.

Refer to figures 3.12.2 and 3.12.3.

<CPHA>: Clock phase select

<CPHA> bit selects one of two, fundamentally different transfer formats.

Refer to figures 3.12.2 and 3.12.3.

<SER1:0>:SEI bit rate select

The following table shows the relationship between the <SER1> and <SER0> control bits and the bit rate for transfers when the SEI is operating as a master. When the SEI is operating as a slave, the serial clock is input from the master, therefore the <SER1> and <SER0> control bits are redundant.

Table 3.12.2 SEI transfer bit rate

<SER1>	<SER0>	Divide-by-rate of internal SEI clock	Transfer rate when $f_c = 24 \text{ MHz}$
0	0	2	4 Mbps
0	1	4	2 Mbps
1	0	8	1 Mbps
1	1	32	250 Kbps

Internal SEI clock: External clock divided by 3.

(2) SEI status register (SESR)

SEI Status Register

	7	6	5	4	3	2	1	0
SESR (009EH)	bit Symbol	SEF	WCOL	SOVF	–	–	–	TMSE
	Read/Write	R						R/W
	After reset	0	0	0				0
Compati- bility mode	Function	SEI transfer complete flag 1: Transfer completed	Write collision flag 1: Write collided	Overflow flag (slave) 1: Overflow occurred				SEI mode select 0: Compati- bility mode 1: Micro DMA mode

SEI Status Register

	7	6	5	4	3	2	1	0	
SESR (009EH)	bit Symbol	–	WCOL	SOVF	–	TSRC	TSTC	TASM	TMSE
	Read/Write		R			R		R/W	
Micro DMA mode	After reset		0	0		0	0	0	0
Read- modify-write instructions prohibited.	Function		Write collision flag 1: Write collided	Overflow flag (slave) 1: Overflow occurred		SEI receive complete flag 1: Receive completed	SEI transmit complete flag 1: Transmit completed	SEI automated shift mode (master) Interrupt mask (slave)	SEI mode select 0: Compati- bility mode 1: Micro DMA mode

<SEF>: Transfer complete flag

Compatibility mode:

The <SEF> flag is automatically set to 1 at the end of a SEI transfer. The <SEF> flag is automatically cleared by reading the SESR register with <SEF> flag set, followed by an access of the SEDR register.

Micro DMA mode:

Always reads as undefined; writes to this flag have no effect.

<WCOL>: Write collision error flag

Compatibility mode:

The <WCOL> flag is automatically asserted if the SEDR register is written while a transfer is in progress. The write itself has no effect on the running transmission. The <WCOL> flag is automatically cleared by reading the SESR register with the <WCOL> bit set followed by an access to the SEDR or SECR register. No interrupt will be generated on the assertion of this flag.

Micro DMA mode:

The <WCOL> flag is automatically asserted if the SEDR register is written while a transfer is in progress. The write itself has no effect on the running transmission. The flag can only be reset by writing a 1 to it. Writing a 0 has no effect. An interrupt will be generated on INTSE0 on a transition from 0 to 1 if the module is configured as a slave and <TASM> bit is equal to 0.

<SOVF>: Slave mode overflow error flag

Master mode:

Always reads as undefined; writes to this flag have no effect.

Slave mode:

Compatibility mode:

The <SOVF> flag is automatically asserted if a new byte has been completely received and the <SEF> flag is still asserted. The <SOVF> flag is automatically cleared by reading the SESR register with the <SOVF> flag set followed by an access to the SEDR register. The <SOVF> flag will also be cleared by switching to master mode. In Compatibility mode, no interrupt will be generated on the assertion of the <SOVF> flag.

Micro DMA mode:

The <SOVF> flag is automatically asserted if a new byte has been completely received and the <TSRC> flag is still asserted. The <SOVF> flag can only be cleared by writing a 1 to it. Writing 0 to it has no effect. INTSE0 is generated with <TASM> = 1 if the <SOVF> flag changes from 0 to 1.

<TSRC>: Receive completion flag

Compatibility mode:

Always reads as undefined; writes to this flag have no effect.

Micro DMA mode:

The <TSRC> flag is set when a receive has been completed, that is when eight cycles have shifted on the SCLK signal. It is cleared by performing a read operation on the SEI data register, by switching to compatibility mode, or by writing a 1 to this flag. Writing a 0 to this flag has no effect. An interrupt INTSE1 will be generated on the assertion of this flag.

<TSTC>: Transmit completion flag

Compatibility mode:

Always reads as undefined; writes to this flag have no effect.

Micro DMA mode:

The <TSTC> flag is set when the transmission of one byte of data is completed, but the timing of the flag depends on the transfer format and master/slave status. Refer to figures 3.12.2 and 3.12.3. It is cleared by performing a write operation on the SEI data register, by switching to compatibility mode or by writing a 1 to this flag. Writing a 0 to this flag has no effect. An interrupt INTSE2 will be generated on the assertion on this flag.

<TASM>: Automated shift mode (master) /INTSE0 interrupt mask (slave)

Compatibility mode:

Always reads as undefined; writes to this flag have no effect.

Micro DMA mode:

The functioning of this bit is determined by the <MSTR> bit setting.

Master mode:

- 0: Disables the automated shift mode.
- 1: Enables the automated shift mode.

In this mode, a read access to the SEI data register SEDR will perform the following functions.

- The SEI data register will be cleared to 00 hex after it has been read.
- A new transfer will be initiated, thus in master mode 8 low bits will be sent, 8 new bits will be received.

The automated shift mode also works when it is combined with a Micro DMA. It has no effect, when SEI is in slave mode.

Slave mode:

This bit functions as a mask for the interrupt INTSE0 generation of the <SOVF> and <WCOL> flags.

- 0: An interrupt will be generated on the <WCOL> flag, but not on the <SOVF> flag.
- 1: An interrupt will be generated on the <SOVF> flag, but not on the <WCOL> flag.

<TMSE>: SEI mode select

- 0: Compatibility mode.
- 1: Micro DMA mode.

Selects the Micro DMA mode, which also allows Micro DMA transfers. It is necessary to disable the SEI system before switching to the Micro DMA mode.

(3) SEI data register (SEDR)

SEI Data Register									
(for transmission)		7	6	5	4	3	2	1	0
	Bit symbol	SED7	SED6	SED5	SED4	SED3	SED2	SED1	SED0
	Read/Write	W							
	After Reset	0	0	0	0	0	0	0	0
SEDR (009FH)									
(for receiving)		7	6	5	4	3	2	1	0
	Bit symbol	SED7	SED6	SED5	SED4	SED3	SED2	SED1	SED0
	Read/Write	R							
	After Reset	0	0	0	0	0	0	0	0

Note) Read-modify-write prohibited.

This register is used to transmit and receive data. When the SEI system is configured as a master, transfers are started by a software write to the SEDR register.

After once starting transmission, please write after checking that the transmission end flag has been set by interrupt or polling when the master device writes to the SEDR register.

Only when the <SEE> bit of the SECR register is “1”, is a read/write to the SEDR register possible.

When the <SEE> bit is “0”, the write access is ignored and “00H” will be read.

3.12.8 SEI System Errors

Two system errors can be detected by the SEI device. The first type of error, a write collision, indicates that an attempt has been made to write data to the SEDR while a transfer was in progress. The second error occurs when the SEI system is configured as a slave and a new byte of data has been completely shifted in by the remote bus master before the old byte could be read.

(1) Write collision error

A write collision occurs if the SEDR register is written while a transfer is in progress. Because the SEDR register is not a double buffer in the direction of the transmission, writing before transfer to the SEDR register is completed is written directly to the SEI shift register. Because this write corrupts any transfer in progress, a write-collision error is generated. The transfer continues undisturbed, and the write data that caused the error is not written to the shifter.

A write collision is normally a slave error because a slave has no control over when a master will initiate a transfer. A master knows when a transfer is in progress, thus, there is no excuse for a master to generate a write-collision error, although the SEI device can detect write collisions in a master as well as in a slave.

In slave mode, a write collision is likely to occur when the master shifts faster than it can be handled by the slave. This occurs when the slave is transferring a new value to the data register after the master has begun the next shift cycle. In this case a write collision occurs.

In Micro DMA mode, an interrupt on INTSE0 will occur, if the module is configured as slave, when the <TASM> bit is set as 0 and the <WCOL> flag shows a positive edge.

(2) Slave mode overflow error

On an SEI bus, the transmission bit rate is determined by the master. At higher bit rates the problem arises whereby a slave might not be able to follow the transmission of a master. This means that the data is shifted in faster than it can be processed by the slave. Therefore the SEI device offers the <SOVF> flag in its status register which allows the detection of a possible loss of data.

The <SOVF> flag will be asserted, when,

- The SEI module is configured as a slave.
- An old byte of data is still waiting to be read when a new byte of data has been completely received.

When <SOVF> is set, the SEDR has been overwritten by new byte data.

Since this error is only arises in the slave mode, the <TASM> bit can be used as an interrupt mask for this flag. An interrupt is generated on INTSE0 only in Micro DMA mode and the <TASM> bit is 1, if the <SOVF> flag in the status register is asserted.

3.12.9 Interrupt Generation

Interrupt processing differs for the two SEI operating modes, which can be selected using the <TMSE> bit in the SESR register. The SEI module is connected to three interrupt channels named INTSE0, INTSE1 and INTSE2.

(1) Compatibility mode

In compatibility mode only the INTSE0 is used. This channel generates an interrupt, if the <SEF> flag in the SESR register shows a transition from 0 to 1. The <SEIE> bit is used as a global interrupt enable/disable.

SEI interrupt channel 0 (INTSE0)	Interrupt on <SEF>
SEI interrupt channel 1 (INTSE1)	Inactive
SEI interrupt channel 2 (INTSE2)	Inactive

(2) Micro DMA mode

In Micro DMA mode all three interrupt channels are used to allow Micro DMA transfers to and from the SEI data register. Interrupt channel 0 generates an interrupt on two different sources. The first type of interrupt is generated on a transition of the <WCOL> flag from 0 to 1 if the module is in slave mode with the <TASM> bit equal to 0. The second type of interrupt is generated on transition of the <SOVF> flag from 0 to 1 if the module is in slave mode with the <TASM> bit equal to 1.

After a completed transfer, both the <TSRC> flag and the <TSTC> flag in the SESR register are asserted simultaneously. However, there is an exception for <CPHA> = 0 in slave mode. Please see “4.1 transfer format of <CPHA> = 0”. Both flags trigger their own interrupt.

The <TSRC> flag generates an interrupt on INTSE1 on a transition from 0 to 1. The <TSRC> flag can be cleared by either reading the SEDR register or by writing a 1 value to this flag.

The <TSTC> flag generates an interrupt on INTSE2 on a transition from 0 to 1. The <TSTC> flag is cleared by either writing the SEDR register or by writing a 1 value to this flag.

For the use of Micro DMAs, INTSE1 and INTSE2 interrupts can be used to trigger a Micro DMA.

INTSE1 interrupt: triggers a Micro DMA read of data from the SEDR register.

INTSE2 interrupt: triggers a Micro DMA write to the SEDR register.

Thus a new transfer is initiated.

SEI interrupt channel 0 (INTSE0)	Interrupt on <WCOL> ^{Note1)} or <SOVF> ^{Note2)}
SEI interrupt channel 1 (INTSE1)	Interrupt on <TSRC>
SEI interrupt channel 2 (INTSE2)	Interrupt on <TSTC>

Note 1: In slave mode, when <TASM> = 0

Note 2: In slave mode, when <TASM> = 1

In Micro DMA mode the <SEIE> bit is redundant. The Interrupts are individually disabled at the interrupt controller.

3.12.10 Use of Micro DMA for SEI (Micro DMA mode)

The use of Micro DMA for larger SEI transfers enables the speeding up of communication on the SEI by

- reducing CPU load for interrupt processing,
- reducing the time gap between two successive transfers.

The Micro DMA transfers can be used in both master and slave modes.

(1) Read/Write Micro DMA transfer

Set the <TMSE>bit of the SESR register to 1 to set to micro DMA mode. Two Micro DMA channels are configured in a way that both the values to be shifted out can be determined and the values shifted in can be stored. However, the transfer will be handled completely by the Micro DMA controller.

[1] Initiation

Two Micro DMA channels must be set up for the transfer. One Micro DMA is triggered on the SEI interrupt channel 1 (INTSE1) to transfer the value that was received from the SEI data register to memory. The other channel (INTSE2) is used to write new data from the memory to the SEI data register. This setting is used to re-initiate transfers in the master mode.

The Micro DMA with the lower channel has to be assigned to the INTSE1 interrupt since it takes precedence over the Micro DMA with the higher channel number.

The Micro DMA transfer is initiated the first time by writing the first transfer value to the SEI data register. The following transfers will be handled automatically by the Micro DMA controller.

Table 3.12.3 SEI setting for micro DMA transfer (Read/Write)

<SEIE>	<SEE>	<MSTR>	<TASM>	<TMSE>
X	1	0: Slave	INTSE0 interrupt mask	1
		1: Master	0	

[2] Micro DMA transfer

Once initiated the Micro DMAs wait to be triggered by a completed transfer. On a completed transfer, both <TSRC> and <TSTC> flags are set to 1, and both the SEI receive completed interrupt pulse INTSE1 and the SEI transmit completed interrupt pulse INTSE2 are generated. Since the Micro DMA channel with the lower channel number takes precedence, the Read Micro DMA is performed before the Write Micro DMA. The Read Micro DMA reads the value from the SEI data register and stores the value at the location specified within the Micro DMA control registers. The read access also clears the <TSRC> flag in effect. After this the Write Micro DMA transfers a value from a specified memory address to the SEI data register. The write access to the data register automatically clears the <TSTC> bit in the SEI status register and starts a new transfer when the module is in master mode. After each Micro DMA transfer, the count registers for both Micro DMA are decreased. This procedure continues until the counters reach the value of 0. A Micro DMA interrupt will be generated to indicate the end of the Micro DMA transfer. An interrupt service routine triggered on the end of the Micro DMA transfer can be used to re-initiate Micro DMA transfers.

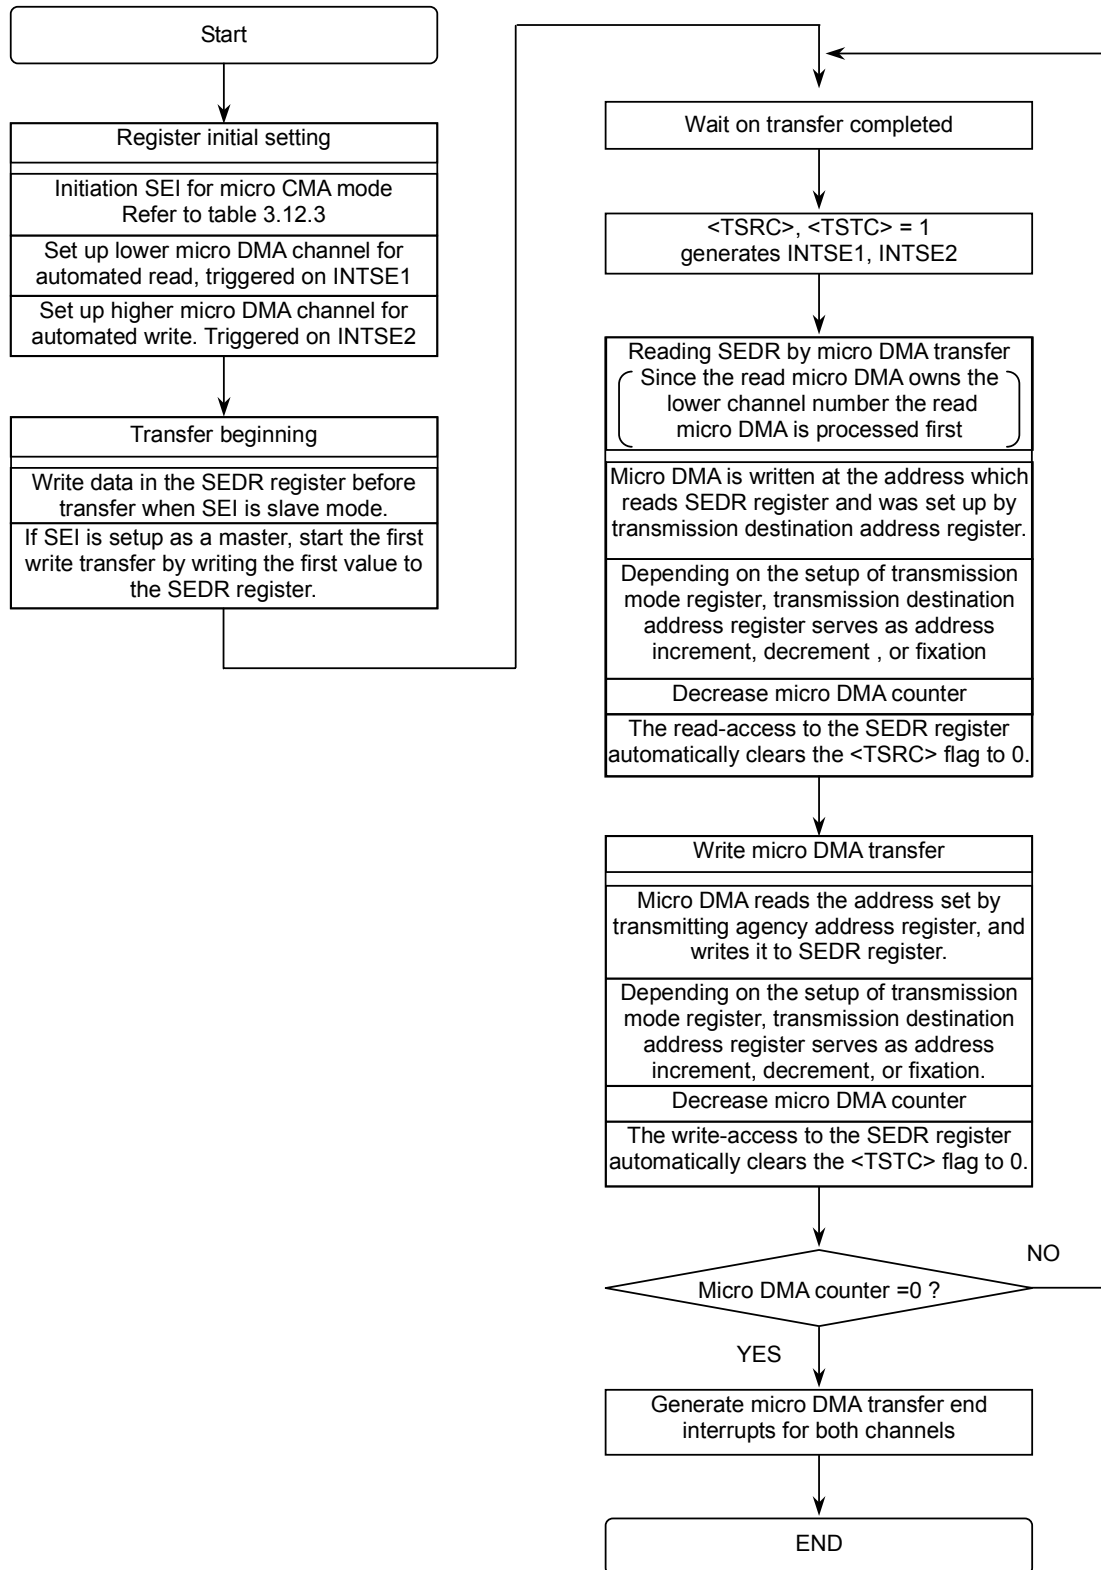

Figure 3.12.7 Flow for Micro DMA read/write transfer

(2) Read-only Micro DMA transfer

This mode is used to shift in larger blocks of data, while “don’t care data” is shifted out (e.g.: reads from serial EEPROM). Only a single Micro DMA is used to store the data read from the SEI data register to a specified RAM area.

[1] Initiation

For this mode the module has to be configured for Micro DMA mode by asserting the <TMSE> bit in the SESR register. When SEI is acting as master, the <TASM> bit has to be set additionally to allow the automated shifting. Just one Micro DMA has to be set up to transfer the received data to a memory location specified within the Micro DMA destination address register. The SEI receive completion interrupt INTSE1 is used to trigger this Micro DMA. The SEI transmit completion interrupt INTSE2 is disabled at the interrupt controller. If SEI is set up as a master, the first transfer has to be initiated by writing the SEI data register.

Table 3.12.4 SEI setting for micro DMA transfer (read-only)

<SEIE>	<SEE>	<MSTR>	<TASM>	<TMSE>
X	1	0: Slave	INTSE0 interrupt mask	1
		1: Master	1	

[2] Micro DMA transfer

After initiating the first transfer, the Micro DMA waits for the transfer to be completed. With the completion of the transfer both the <TSRC> and <TSTC> flags in the SEI status register are asserted. On the assertion of the <TSRC> flag an interrupt is generated to trigger the Micro DMA. The <TSTC> flag will be asserted simultaneously and will remain set till the end of the block transfer.

The Micro DMA moves the received value from the SEI data register to the memory location specified in its destination address register. When the SEDR register is read, the SEDR register (shift register) is cleared to “00H” automatically because <TASM> bit is 1. Simultaneously, a new transfer is started automatically. This procedure will repeat until the Micro DMA counter reaches a value of 0.

Moreover, after the first transfer is completed, the <TSTC> flag remains as set at 1, unless cleared.

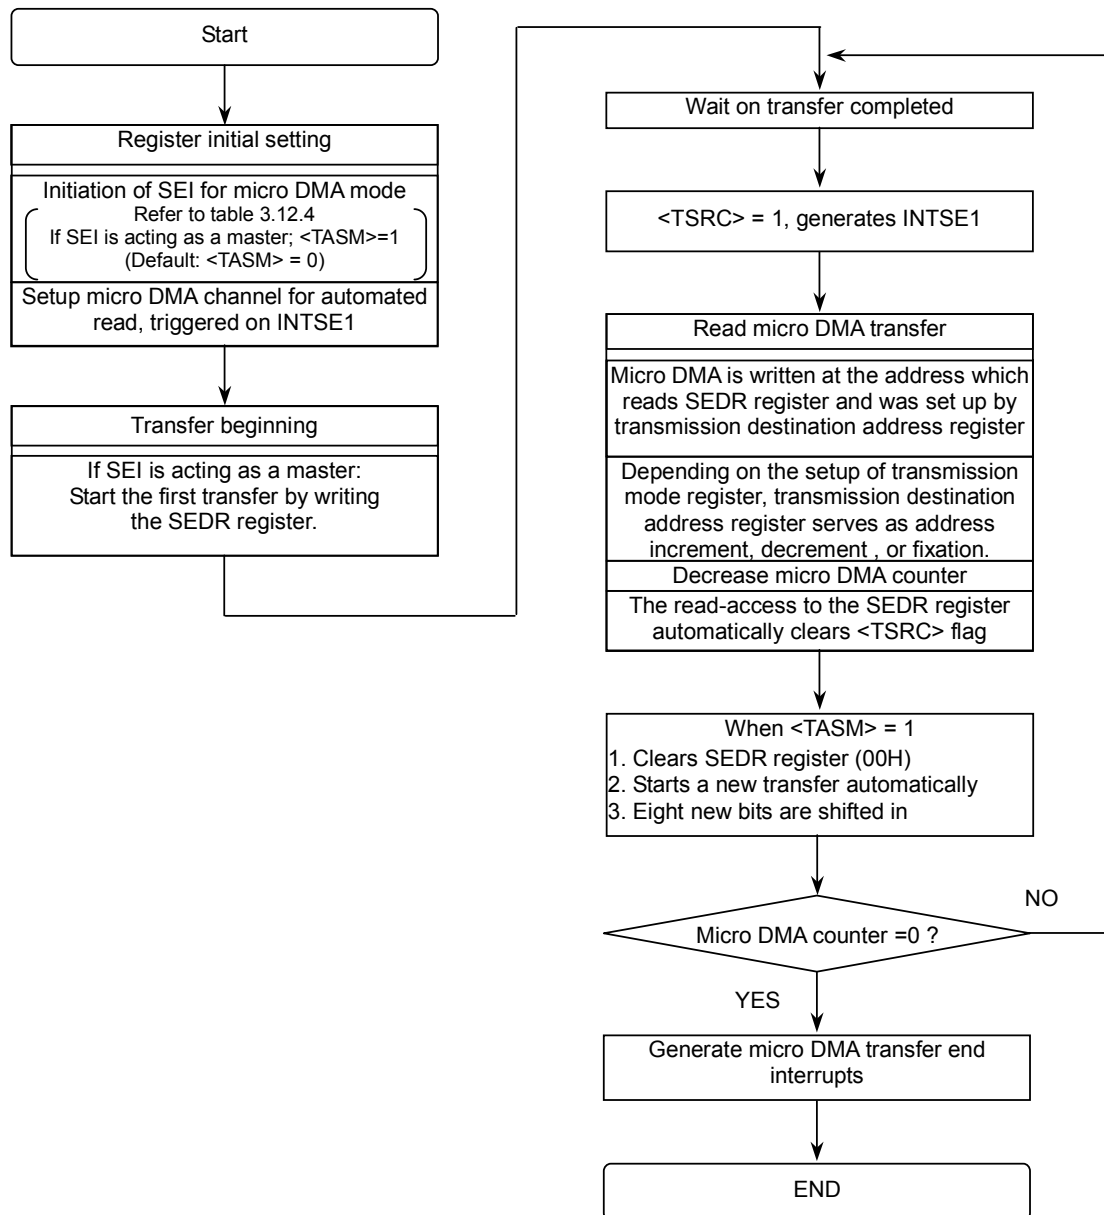

Figure 3.12.8 Flowchart for Micro DMA read-only transfer

(3) Write-only Micro DMA transfer

The write-only transfer mode is used to transmit larger blocks of data while the incoming data is ignored. Only a single Micro DMA is used to transfer new transmit data from a memory location specified by the Micro DMA source address register to the SEI data register.

[1] Initiation

For this mode the module has to be configured for Micro DMA mode by asserting the <TMSE> bit in the SESR register. One of the Micro DMA channels has to be set up for the automated write to the SEI data register. This Micro DMA is triggered by the SEI transmit completion interrupt INTSE2. The SEI receive completion interrupt INTSE1 is disabled at the interrupt controller. If SEI is set up as a master, the first transfer is initiated by writing the first value to the SEI data register.

Table 3.12.5 SEI setting for micro DMA transfer (write-only)

<SEIE>	<SEE>	<MSTR>	<TASM>	<TMSE>
X	1	0: Slave	INTSE0 interrupt mask	1
		1: Master	0	

[2] Micro DMA transfer

After starting the first transfer, the Micro DMA waits for the transfer to be completed. On completion, both the <TSRC> and <TSTC> flags in the SEI status register are asserted. Disregard the <TSRC> flag and the <SOVF> flag as they are no longer used. After the first transfer is completed, the <TSRC> flag remains as set at 1, unless cleared. If once set at 1, the <SOVF> flag also remains at 1 unless cleared. The <TSTC> flag generates an interrupt, which will trigger the Micro DMA transfer.

The Micro DMA reads a value from the memory address specified in its source register and transfers it to the SEI data register. The write access to the SEI data register clears the <TSTC> flag and starts a new transfer on the SEI bus when the module is in master mode. This procedure continues until the Micro DMA counter reaches a value of 0.

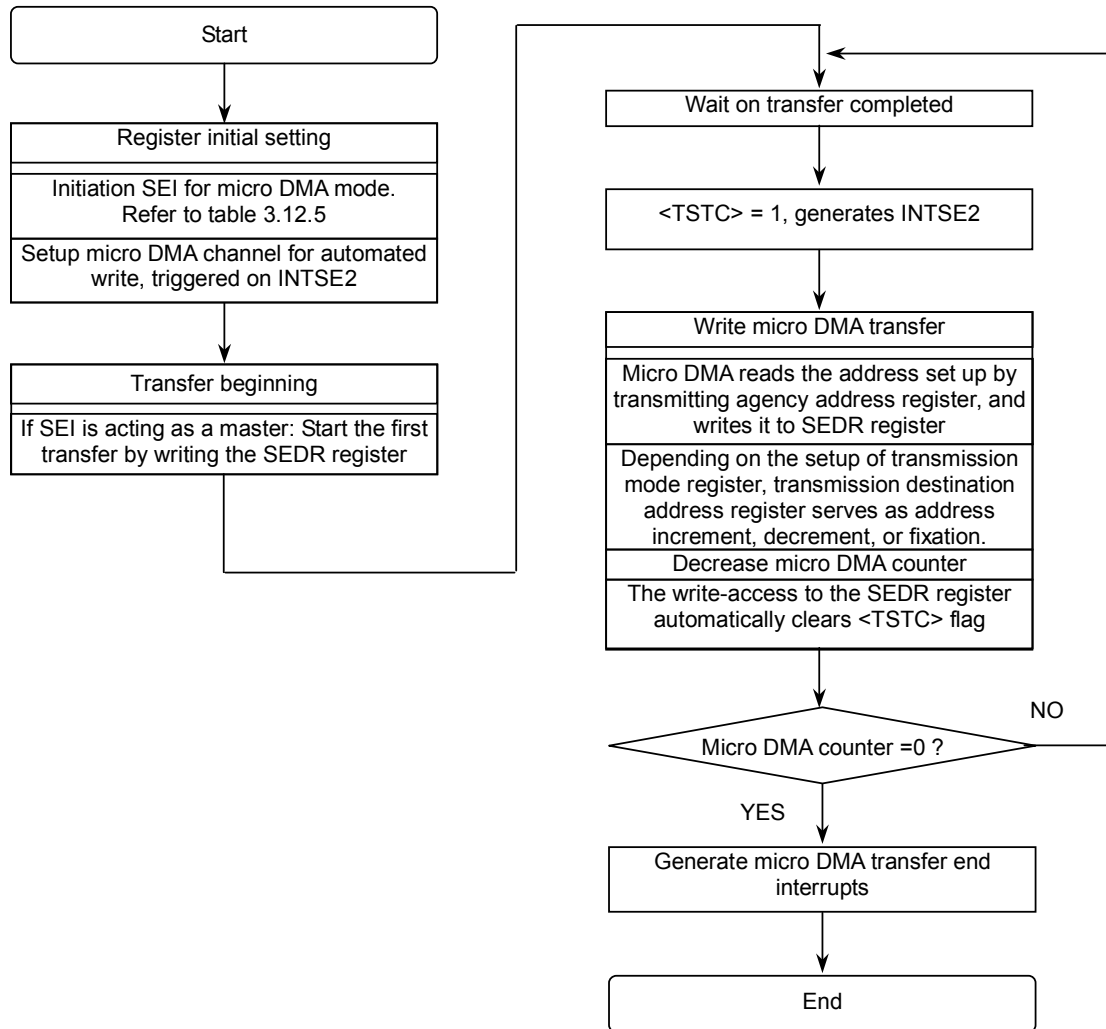

Figure 3.12.9 Flowchart for Micro DMA write-only transfer

3.13 Watchdog Timer (Runaway Detection Timer)

The TMP95CU54A incorporates a watchdog timer for detecting a runaway (out-of-control) condition.

The watchdog timer (WDT) returns the CPU to its normal state when it detects the start of a CPU runaway due to, for example, noise. When the watchdog timer detects a runaway, it generates an INTWD (non-maskable) interrupt to notify the CPU of the condition.

In addition, the runaway detection result can be used for a forcible reset of the microcontroller itself. The watchdog timer consists of a 22-step binary counter with $2/f_c$ as the input clock, and a control block. Figure 3.13.1 is a block diagram of the watchdog timer (WDT).

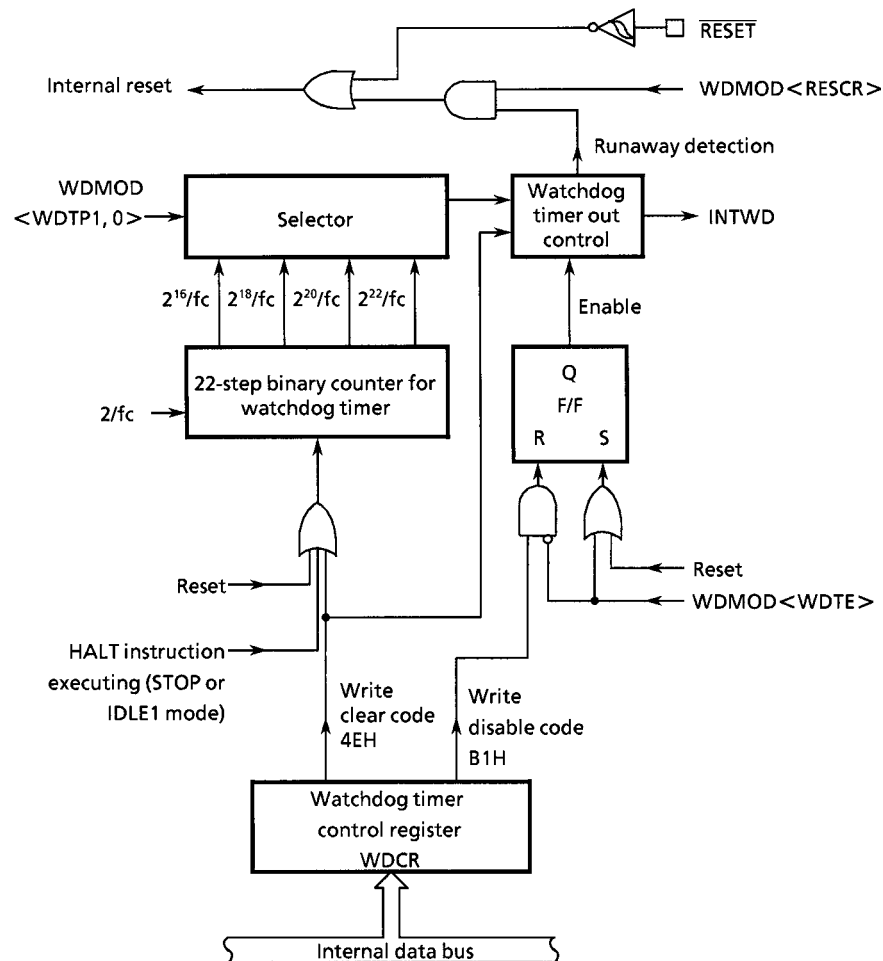

Figure 3.13.1 Block diagram of watchdog timer

3.13.1 Watchdog timer registers

The watchdog timer (WDT) is controlled by two control registers. Figure 3.13.2 shows watchdog timer mode control register WDMOD and watchdog timer control register WDCR.

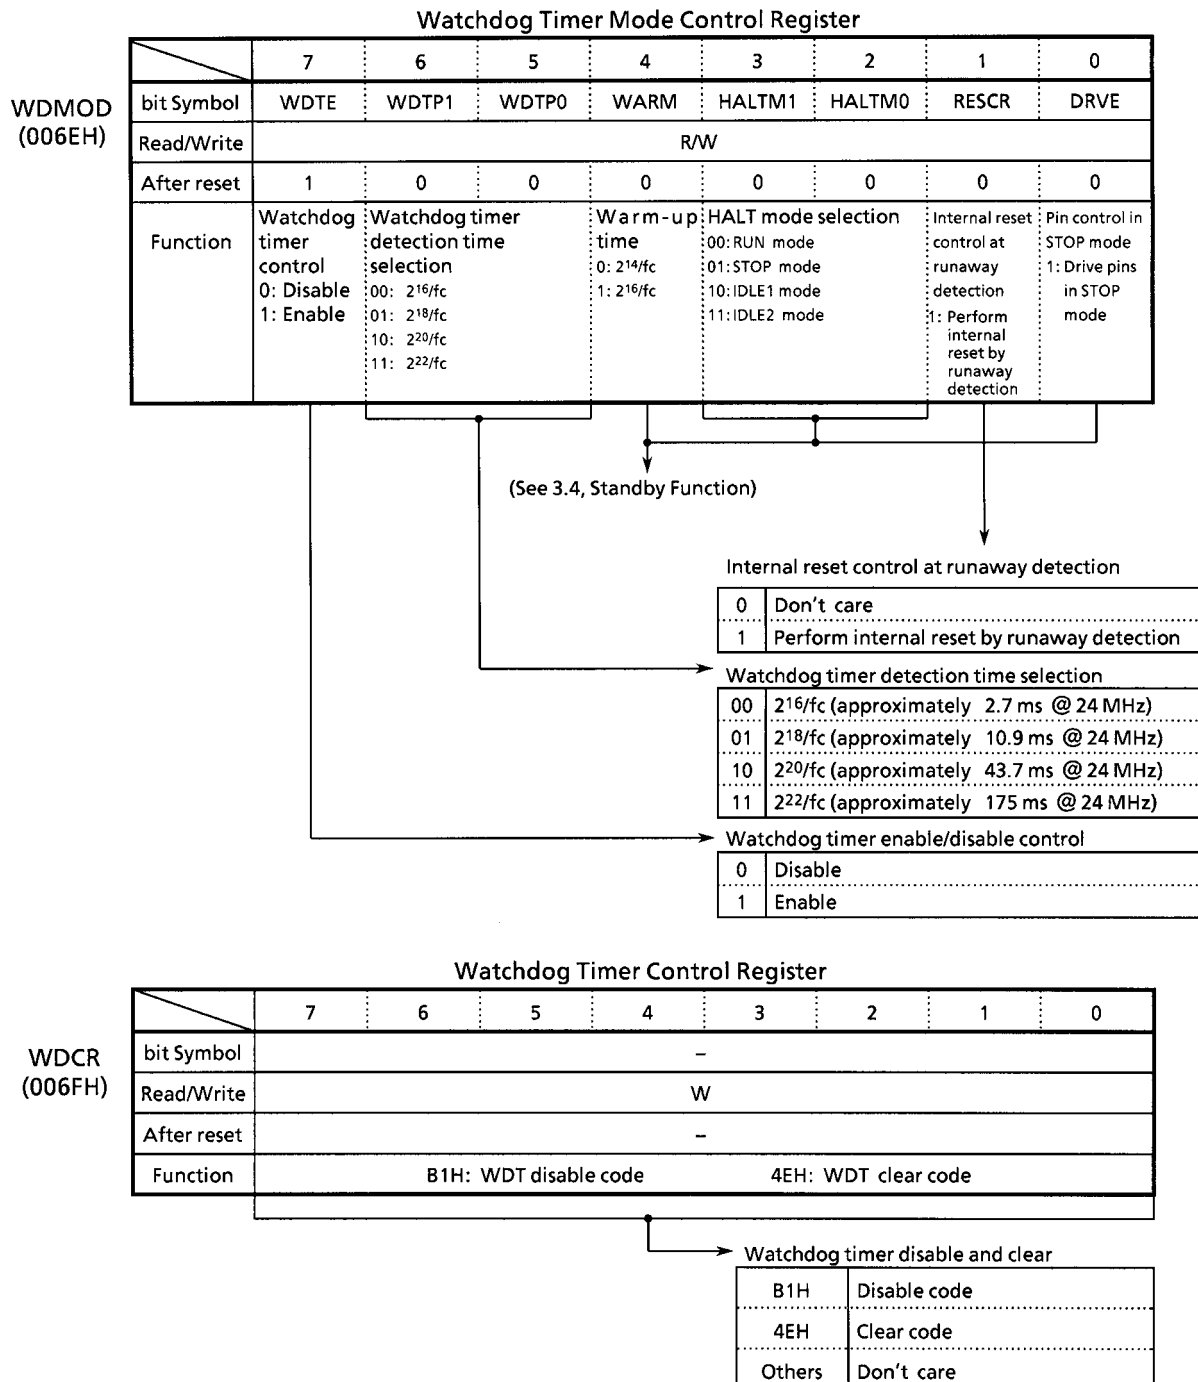

Figure 3.13.2 Watchdog Timer Related Registers

(1) Watchdog timer mode control register (WDMOD)

[1] Setting watchdog timer detection time <WDTP1:0>

This 2-bit register is used to set the watchdog timer interrupt time for detecting a runaway. After a reset, WDMOD <WDTP1:0> is set to 00, which sets a detection time of $2^{16}/f_c$ [s]. (The number of states is approximately 32,768.)

[2] Watchdog timer enable/disable control <WDTE>

After a reset, WDMOD<WDTE> is initialized to 1, enabling the watchdog timer.

Disabling the watchdog timer requires both clearing this bit to 0 and writing the disable code B1H in watchdog timer control register WDCR. This two-step process is an insurance against an out-of-control system disabling the watchdog timer.

To return from disable state to enable state, simply set <WDTE> to 1.

[3] Runaway detection time internal reset control <RESCR>

This register determines whether or not the watchdog timer resets itself on detection of a runaway. Setting WDMOD <RESCR> to 1 forcibly resets the microcontroller after detection of a runaway. On reset, <RESCR> is initialized to 0. Therefore, detection of a runaway will not trigger an internal reset. In such a case, the watchdog timer holds the runaway detection state until the clear code is written to WDCR.

(2) Watchdog timer control register WDCR

This register is used to disable the watchdog timer functions and to clear the binary counter.

• Disable control

After clearing WDMOD<WDTE> to 0, write the disable code B1H to WDCR to disable the watchdog timer.

		7	6	5	4	3	2	1	0	
[WDMOD	←	0	-	-	-	-	X	X	Clear <WDTE> to 0.
	WDCR	←	1	0	1	1	0	0	1	Write disable code B1H.

Note: X : Don't care - : No change

• Watchdog timer clear control

Writing clear code 4EH to WDCR clears the binary counter and resumes the count.

WDCR ← 0 1 0 0 1 1 1 0 Write clear code 4EH.

3.13.2 Description of operation

After the detection time set by the watchdog timer mode register WDMOD <WDTP1:0> is reached, the watchdog timer generates interrupt INTWD. The watchdog timer detection time can be selected from $2^{16}f/c$, $2^{18}f/c$, $2^{20}f/c$, and $2^{22}f/c$. The binary counter for the watchdog timer must be cleared to 0 by software (by instruction) before the INTWD interrupt is generated. If the CPU malfunctions (is out of control) due to factors such as noise, and does not execute an instruction to clear the binary counter, the binary counter overflows and generates interrupt INTWD. The CPU interprets the INTWD interrupt as a malfunction (runaway condition) detection signal, which can be used to start program-based anti-malfunction measures to return the system to normal (normal mode).

Runaway detection can also be used for an internal reset (reset mode). To perform an internal reset by runaway detection, first set WDMOD <RESCR> to 1.

The INTWD interrupt generation cycle is twice the watchdog timer detection time selected by <WDTP1:0>.

Figure 3.13.3 Normal Mode

Figure 3.13.4 Reset Mode

The watchdog timer operates during RUN and IDLE2 modes. While an INTWD interrupt does not occur during IDLE2 mode, to prevent an INTWD interrupt being triggered immediately after the halt release, disable the watchdog timer. The watchdog timer is halted in IDLE1 and STOP modes.

As the binary counter continues counting during bus release (when $\overline{\text{BUSA}}\text{K}$ goes low), set the runaway detection time in accordance with the bus release time. If the watchdog timer detects a runaway condition during bus release, the watchdog timer generates an INTWD interrupt immediately after the bus release.

The watchdog timer starts operating immediately after reset release.

- Example:
- [1] Clear the binary counter.
WDCR ← 0 1 0 0 1 1 1 0 Write clear code 4EH.
 - [2] Set the watchdog timer detection time to $2^{18}/f_c$.
WDMOD ← 1 0 1 - - - X X
 - [3] Disable the watchdog timer.
WDMOD ← 0 - - - - X X Clear <WDTE> to 0.
WDCR ← 1 0 1 1 0 0 0 1 Write disable code B1H.
 - [4] Select IDLE1 mode.
WDMOD ← 0 - - - 1 0 X X Disable WDT and set IDLE1 mode.
WDCR ← 1 0 1 1 0 0 0 1
Execute HALT instruction. Set HALT mode.
 - [5] Select IDLE2 mode.
WDMOD ← 0 - - - 1 1 X X Disable WDT and set IDLE2 mode.
WDCR ← 1 0 1 1 0 0 0 1
Execute HALT instruction. Set HALT mode.
 - [6] Select STOP mode. (Warm-up time $2^{16}/f_c$)
WDMOD ← - - - 1 0 1 X X Set STOP mode.
Execute HALT instruction. Set HALT mode.

Note: X : Don't care - : No change

3.14 Bus Release Function

The TMP95CU54A has a bus request pin ($\overline{\text{BUSRQ}}$, shared with P53) for releasing the bus, and a bus acknowledge pin ($\overline{\text{BUSAK}}$, shared with P54). These pins are set by the P5CR and P5FC registers.

3.14.1 Description of operation

When a low level signal is input to the $\overline{\text{BUSRQ}}$ pin, the TMP95CU54A recognizes a bus release request. When the current bus cycle terminates, the address bus (A23 to A0) and the bus control signals ($\overline{\text{RD}}$, $\overline{\text{WR}}$, $\overline{\text{HWR}}$) first go high. Then these signals and the data bus (D15 to D0) output buffer are set to off, and the $\overline{\text{BUSAK}}$ pin outputs a low signal. This sequence indicates that the bus is released.

During bus release, TMP95CU54A disables all access to the internal I/O registers, although internal I/O functions are not affected. Accordingly, the watchdog timer continues to count up during bus release. When using the bus release function, set the runaway detection time in accordance with the bus release time.

3.14.2 Pin states when bus is released

Table 3.14.1 shows the pin states when the bus is released.

Table 3.14.1 Pin States at Bus Release

Pin Name	Pin State at Bus Release	
	Port Mode	Function Mode
P07 to P00 (D7 to D0) P17 to P10 (D15 to D8)	No change	Goes to high impedance.
P27 to P20 (A23 to A16) P37 to P30 (A15 to A8) P47 to P40 (A7 to A0) P50 ($\overline{\text{RD}}$) P51 ($\overline{\text{WR}}$)	No change	Goes to high impedance. (Goes high immediately before bus release.)
P52 ($\overline{\text{HWR}}$)	No change	Turns output buffer off. Internal pull-up resistors are added regardless of the output latch value. (Goes high immediately before bus release.)

4. Electrical Characteristics

4.1 Absolute Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	V_{CC}	- 0.5 to + 6.5	V
Input Voltage	V_{IN}	- 0.5 to $V_{CC} + 0.5$	V
Output current (total)	ΣI_{OL}	+ 120	mA
Output current (total)	ΣI_{OH}	- 120	mA
Power Dissipation ($T_a = + 85^{\circ}\text{C}$)	P_D	600	mW
Soldering Temperature (10 s)	T_{SOLDER}	+ 260	$^{\circ}\text{C}$
Storage Temperature	T_{STG}	- 65 to + 150	$^{\circ}\text{C}$
Operating Temperature	T_{OPR}	- 40 to + 85	$^{\circ}\text{C}$

Note: The absolute maximum ratings are rated values which must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any absolute maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no absolute maximum rating value will ever be exceeded.

4.2 DC Electrical Characteristics

 $V_{CC} = +5\text{ V} \pm 10\%$, $T_a = -40\text{ to }+85^\circ\text{C}$ ($f_c = 8\text{ to }24\text{ MHz}$)

Parameter	Symbol	Test Condition	Min	Max	Unit
Input Low Voltage (D0 to 15)	V_{IL}		-0.3	0.8	V
Port 2 to A (except P56, P70, P72, P73, P75)	V_{IL1}		-0.3	$0.3 V_{CC}$	V
RESET, NMI, INT0 to 4	V_{IL2}		-0.3	$0.25 V_{CC}$	V
EA, AM8/16	V_{IL3}		-0.3	0.3	V
X1	V_{IL4}		-0.3	$0.2 V_{CC}$	V
Input High Voltage (D0 to 15)	V_{IH}		2.2	$V_{CC} + 0.3$	V
Port 2 to A (except P56, P70, P72, P73, P75)	V_{IH1}		$0.7 V_{CC}$	$V_{CC} + 0.3$	V
RESET, NMI, INT0 to 4	V_{IH2}		$0.75 V_{CC}$	$V_{CC} + 0.3$	V
EA, AM8/16	V_{IH3}		$V_{CC} - 0.3$	$V_{CC} + 0.3$	V
X1	V_{IH4}		$0.8 V_{CC}$	$V_{CC} + 0.3$	V
Output Low Voltage	V_{OL}	$I_{OL} = 1.6\text{ mA}$		0.45	V
Output High Voltage	V_{OH}	$I_{OH} = -400\text{ }\mu\text{A}$	2.4		V
	V_{OH1}	$I_{OH} = -100\text{ }\mu\text{A}$	$0.75 V_{CC}$		V
	V_{OH2}	$I_{OH} = -20\text{ }\mu\text{A}$	$0.9 V_{CC}$		V
Darlington Drive Current (8 Output Pins max.)	I_{DAR}	$V_{EXT} = 1.5\text{ V}$ $R_{EXT} = 1.1\text{ k}\Omega$	-1.0	-3.5	mA
Input Leakage Current	I_{LI}	$0.0 \leq V_{in} \leq V_{CC}$	0.02 (Typ)	± 5	μA
Output Leakage Current	I_{LO}	$0.2 \leq V_{in} \leq V_{CC} - 0.2$	0.05 (Typ)	± 10	μA
Operating Current (NORMAL)	I_{CC}	$f_c = 24\text{ MHz}$	70 (Typ)	85	mA
RUN			35 (Typ)	50	mA
IDLE2			30 (Typ)	40	mA
IDLE1			5 (Typ)	10	mA
STOP ($T_a = -40\text{ to }+85^\circ\text{C}$) ($T_a = -20\text{ to }+70^\circ\text{C}$)		$0.2 \leq V_{in} \leq V_{CC} - 0.2$	0.5 (Typ)	100	μA
				50	μA
Power Down Voltage (@STOP, RAM Back up)	V_{STOP}	$V_{IL2} = 0.2 V_{CC}$, $V_{IH2} = 0.8 V_{CC}$	2.0	6.0	V
Pull Up Registance	R_{RP}		45	160	k Ω
Pin Capacitance	C_{IO}	$f_c = 1\text{ MHz}$		10	pF
Schmitt Width RESET, NMI, INT0 to 4	V_{TH}		0.4	1.0 (Typ)	V

Note 1: Typical values are for $T_a = +25^\circ\text{C}$, $V_{CC} = +5\text{ V}$

Note 2: I_{DAR} guarantees up to eight pins from any output port.

Refer: I_{DAR} definition diagram

4.3 AC Electrical Characteristics

 $V_{CC} = +5\text{ V} \pm 10\%$, $T_a = -40\text{ to }+85^\circ\text{C}$
(f_c = 8 MHz to 24 MHz)

No.	Parameter	Symbol	Variable		24 MHz		Unit
			Min	Max	Min	Max	
1	Oscillation cycle (= x)	t _{OSC}	42	125	42		ns

AC measuring conditions

- Output level: High 2.2 V / Low 0.8 V, CL = 50 pF
- Input level: High 2.4 V / Low 0.45 V (D0 to D15)
High 0.8×V_{CC} / Low 0.2×V_{CC} (except for D0 to D15)

(1) Read cycle

(2) Write cycle

4.4 Serial Channel Timing

(1) I/O interface mode

[1] SCLK input mode

$V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

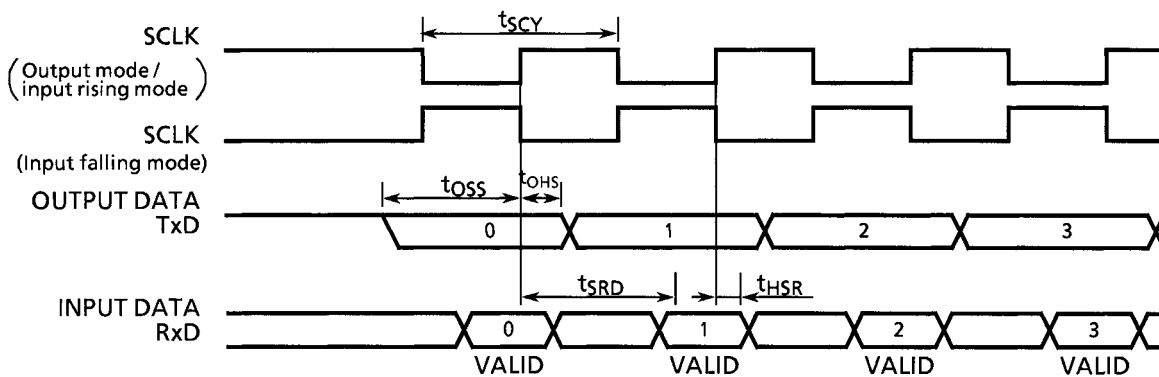

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
SCLK cycle	t_{SCY}	16x		0.667		μs
Output Data \rightarrow SCLK rise/fall*	t_{OSS}	$t_{SCY}/2 - 5x - 50$		75		ns
SCLK rise/fall* \rightarrow Output Data hold	t_{OHS}	$5x - 100$		108		ns
SCLK rise/fall* \rightarrow input data hold	t_{HSR}	0		0		ns
SCLK rise/fall* \rightarrow valid data input	t_{SRD}		$t_{SCY} - 5x - 100$		358	ns

*) SCLK rise/fall: In SCLK rising edge mode, SCLK rising edge timing; in SCLK falling edge mode, SCLK falling edge timing

[2] SCLK output mode

$V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
SCLK cycle (programmable)	t_{SCY}	16x	8192x	0.667	341.3	μs
Output Data \rightarrow SCLK rising edge	t_{OSS}	$t_{SCY} - 2x - 150$		433		ns
SCLK rising edge \rightarrow Output Data hold	t_{OHS}	$2x - 80$		3		ns
SCLK rising edge \rightarrow Input Data hold	t_{HSR}	0		0		ns
SCLK rising edge \rightarrow valid data input	t_{SRD}		$t_{SCY} - 2x - 150$		433	ns

(2) UART mode (SCLK0 to 1 external input)

$V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
SCLK cycle	t_{SCY}	$4x + 20$		187		ns
Low-level SCLK pulse width	t_{SCYL}	$2x + 5$		88		ns
High-level SCLK pulse width	t_{SCYH}	$2x + 5$		88		ns

4.5 AD Conversion Characteristics

 $V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit
AD analog reference supply voltage (+)	V_{REFH}		$V_{CC} - 0.2$		V_{CC}	V
AD analog reference supply voltage (-)	V_{REFL}		V_{SS}		$V_{SS} + 0.2$	
Analog reference voltage	AV_{CC}		$V_{CC} - 0.2$		V_{CC}	
Analog reference voltage	AV_{SS}		V_{SS}		$V_{SS} + 0.2$	
Analog input voltage	V_{AIN}		V_{REFL}		V_{REFH}	
Analog reference voltage supply current	$\langle V_{REFON} \rangle = 1$	I_{REF}	$V_{CC} = +5V \pm 10\%$		3.7	mA
	$\langle V_{REFON} \rangle = 0$		$V_{CC} = +5V \pm 10\%$	0.02	5.0	μA
Total tolerance (excludes quantization error)	E_T	$V_{CC} = +5V \pm 10\%$		± 1	± 3	LSB

Note 1: $1\text{LSB} = (V_{REFH} - V_{REFL}) / 2^{10} [\text{V}]$

Note 2: Power supply current ICC from the V_{CC} pin includes the power supply current from the AV_{CC} pin.

4.6 Event Counter (External Input Clocks: TI0, TI4, TI8, TI9, TIA, TIB)

 $V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
External input clock cycle	t_{VCK}	$8x + 100$		433		ns
External low-level input clock pulse width	t_{VCKL}	$4x + 40$		207		ns
External high-level input clock pulse width	t_{VCKH}	$4x + 40$		207		ns

4.7 Interrupt Operation

 $V_{CC} = +5V \pm 10\%$, $T_a = -40$ to $+85^\circ\text{C}$ ($f_c = 8$ to 24 MHz)

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
NMI, INT0 to 4 low-level pulse width	t_{INTAL}	$4x$		167		ns
NMI, INT0 to 4 high-level pulse width	t_{INTAH}	$4x$		167		ns
INT5 to INT8 low-level pulse width	t_{INTBL}	$8x + 100$		433		ns
INT5 to INT8 high-level pulse width	t_{INTBH}	$8x + 100$		433		ns

4.8 Bus Request/Bus Acknowledge Timing

V_{CC} = +5 V ± 10%, T_a = -40 to +85°C (f_c = 8 to 24 MHz)

Parameter	Symbol	Variable		24 MHz		Unit
		Min	Max	Min	Max	
BUSRQ setup time for CLK	t _{BRC}	120		120		ns
CLK → BUSAK fall	t _{CBAL}		2.0x + 120		203	ns
CLK → BUSAK rise	t _{CBAH}		0.5x + 40		61	ns
Time from output buffer off until BUSAK falling edge	t _{ABA}	0	80	0	80	ns
Time from BUSAK rising edge until output buffer on	t _{BAA}	0	80	0	80	ns

Note 1: When $\overline{\text{BUSRQ}}$ goes to low level to request bus release, if the current bus cycle is not yet complete due to a wait, the bus is not released until the wait is completed.

Note 2: The dotted line indicates only that the output buffer is off, not that the signal is at middle level. Immediately after bus release, the signal level prior to the bus release is held dynamically by the external load capacitance. Therefore, designs should allow for the fact that when using an external resistor or similar to fix the signal level while the bus is released, after bus release, a delay occurs before the signal goes to its fixed level (due to the CR time constant). The internal programmable pull-up resistor continues to function in accordance with the internal signal level.

5. List of Special Function Registers (SFR) and the Mailbox RAM

The special function registers (SFR), which control the input/output ports and peripheral components, are allocated 160 bytes within the 000000H to 00009FH address range and 64 bytes within the 002300H to 00233FH address range.

The mailbox RAM is allocated 256 bytes within the 002200H to 0022FFH address range.

The registers built into the TMP95CU54A cannot be accessed from outside the TMP95CU54A.

6. Diagram of Equivalent Circuit in Port Block

- Reading circuit diagrams

The TMP95CU54A uses essentially the same gate symbols as the standard CMOS logic IC (74HCxxx) series.

The following lists the special symbols.

STOP: This symbol sets the HALT mode setting register to STOP mode (WDMOD <HALTM1:0> = 0, 1). When the CPU executes the HALT instruction, STOP is active 1.

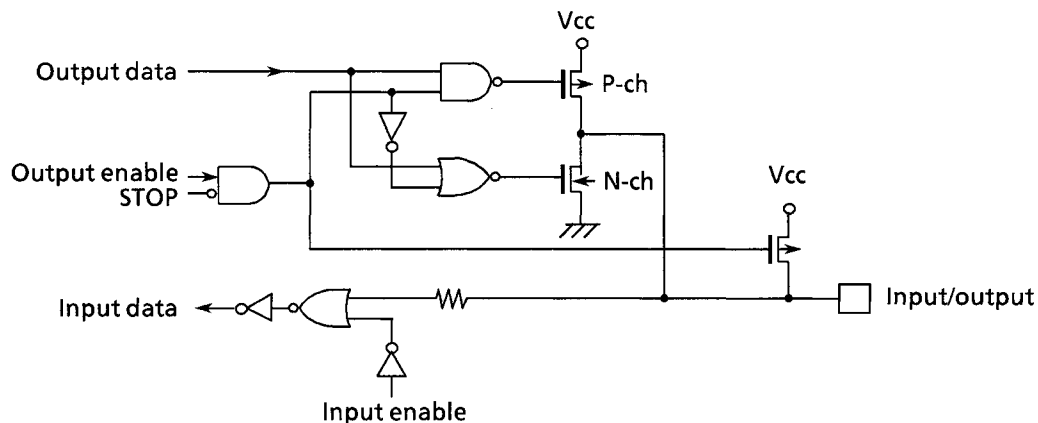

Note that when the drive enable bit WDMOD<DRVE> is set to 1, STOP remains at 0.

- The input protection resistor operates in the range of tens to hundreds of ohms.

- P0 (D0 to D7), P1 (D8 to D15), P2 (A16 to A23), P31 to P37 (A9 to A15), P4 (A0 to A7)

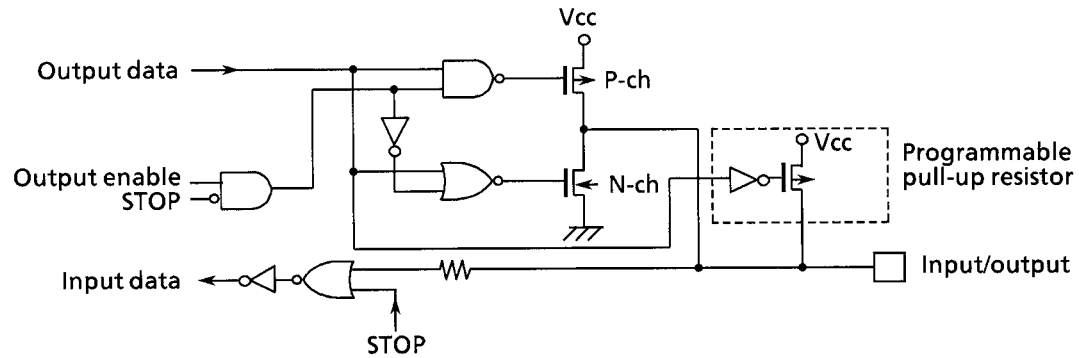

- P30 (A8)

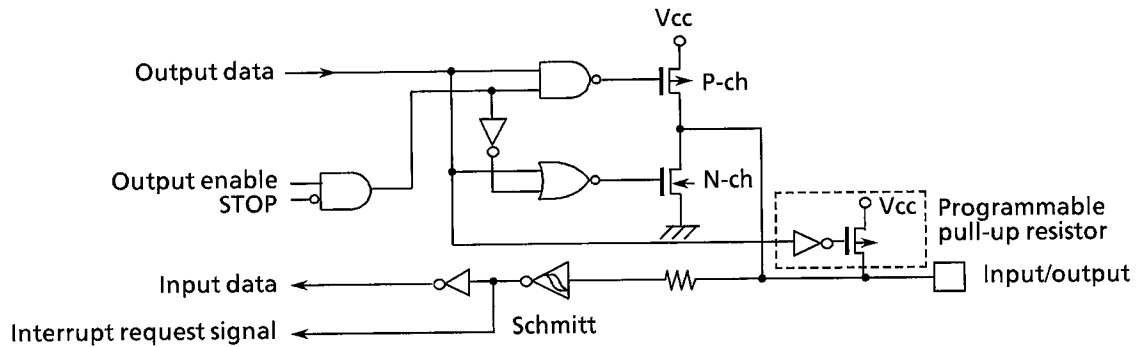

- P50 (\overline{RD}), P51 (\overline{WR})

■ P52 to 55, P81, P82, P84, P85, P86, P87

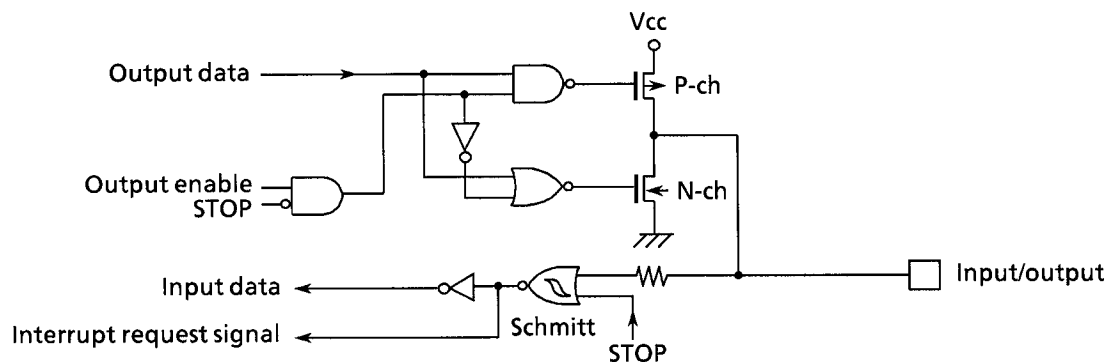

■ P56 (INT0)

■ P57 (CLKOUT)

■ P70 (INT1), P72 (INT2), P73 (INT3), P75 (INT4)

■ P60, P71, P74, P9

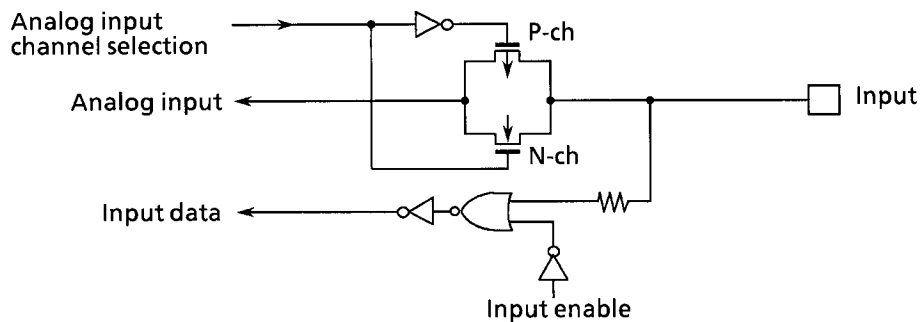

■ P61 (MOSI), P62 (MISO), P63 (SCLK)

■ P80 (TxD0), P83 (TxD1)

■ PA0 to 2 (AN0 to 2), PA4 to 7 (AN4 to 7)

■ PA3 (AN3)

■ $\overline{\text{NMI}}$

■ CLK

■ \overline{EA}

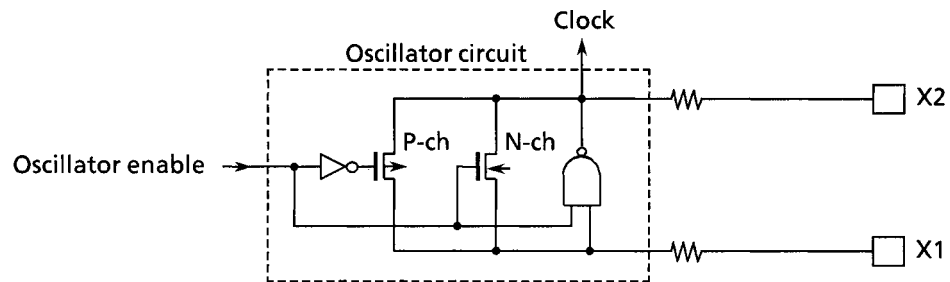

■ AM8/16

■ \overline{RESET}

■ X1, X2

■ VREFH, VREFL

7. Use Precautions and Restrictions

(1) Special Notations and Words

- [1] Description of internal I/O registers: Register symbol<bit symbol>

Example: T8RUN<T0RUN> ... The T0RUN bit of the T8RUN register

- [2] Read-modify-write instructions

Instructions which tell the CPU to read the data in memory, manipulate them, then write them back to memory are called read-modify-write instructions.

Example 1) SET 3, (T8RUN) ... Sets bit 3 of the T8RUN register.

Example 2) INC 1, (100H) ... Adds 1 to the data at address 100H.

- TLCS-900 read-modify-write instructions

Conversion instruction

EX (mem), R

Arithmetic operations

ADD (mem), R/# ADC (mem), R/#

SUB (mem), R/# SBC (mem), R/#

INC #3, (mem) DEC #3, (mem)

Logic operations

AND (mem), R/# OR (mem), R/#

XOR (mem), R/#

Bit manipulation

STCF #3/A, (mem) SET #3, (mem)

RES #3, (mem) TSET #3, (mem)

CHG #3, (mem)

Rotate, shift

RLC (mem) RRC (mem)

RL (mem) RR (mem)

SLA (mem) SRA (mem)

SLL (mem) SRL (mem)

RLD A, (mem) RRD A, (mem)

- [3] One state

The single cycle resulting from dividing the oscillation frequency by 2 is called "one state".

Example: At oscillation frequency 24 MHz

$$2/24 \text{ MHz} = 83 \text{ ns} = 1 \text{ state}$$

(2) Use Precautions and Limitations

[1] \overline{EA} pin, AM8/ $\overline{16}$ pin

This pin is connected to the VCC pin. Do not alter the level while the pin is active.

[2] Warm-up counter

When releasing STOP mode (by interrupt, for example) in a system that uses an external oscillator, a warm-up time is required until the system clock is output. The warm-up counter operates during the warm-up time.

[3] Programmable pull-up resistor

The pull-up resistor of a port can only be set to programmable or non-programmable in input port mode. When using a port as an output port, its pull-up resistor cannot be set to programmable.

[4] Watchdog timer

As the watchdog timer is enabled after a reset, disable the watchdog timer when it is not required.

Note that during bus release, the I/O block, including the watchdog timer, still operates.

[5] CPU (Micro DMA)

Only "LDC cr, r" and "LDC r, cr" can write or read data to or from control registers (eg, transfer source register DMASx) in the CPU.

[6] As this device does not support minimum mode, do not use the MIN instruction.

[7] POP SR instruction

Please execute POP SR instruction during DI condition.

[8] Releasing the HALT mode by requesting an interruption

Usually, interrupts can release all halts status. However the interrupts (= NMI and INT0) which can release the HALT mode may not be able to do so if they are input during the period when the CPU is shifting to the HALT mode (for about 3 clock of f_c) with IDLE1 or STOP mode (RUN and IDLE2 are not applicable to this case). (In this case, an interrupt request is kept on hold internally)

If another interrupt is generated after it has shifted to completely HALT mode, halt status can be released without difficulty. The priority of this interrupt is compared with that of the interrupt kept on hold internally, and the interrupt with the higher priority is handled first followed by the other interrupt.
